At 2 in. pressure when using the plain nozzle the burner was silent, and three-quarters of the mantle was heated. At 4 in. pressure the burner was slightly noisy and the mantle was fully heated, with a small amount of flame showing above the mantle ring. This could not be eliminated by increasing the primary air supply, any attempt to do so resulting in back-firing. A test was made at 4 in. pressure after fitting to the burner one of the usual open types of Vitreosil globes, the air and gas adjustments remaining unaltered. The burner became slightly more noisy and would back-fire more readily. The air-gas ratio was very little affected, but rather less products of combustion were taken-in with the primary air, probably because of the more effective air circulation around the burner when fitted with the globe.

The first tests with the air shutter fully open and the gas unlighted, using the pepper-box nozzle, gave air-gas ratios almost indistinguishable from those with the plain nozzle, so that the perforated end did not offer any appreciably greater resistance to the flow of gas and air than the plain nozzle. Slightly lower air-gas ratios were obtained with the pepper-box nozzle, when the air opening was throttled to correspond with the conditions of tests for the plain nozzle (gas unlighted). The difference, however, was very small, and there were slight changes in sp. gr. of gas, in atmospheric conditions, and in the re-setting of the air shutter, which would easily account for the observed changes in air-gas ratio.

The pepper-box nozzle would permit the air shutter to be opened fully, and back-firing did not occur, although the air-gas ratios obtained were some 20 p.ct. higher than could be used with the plain nozzle at corresponding gas rates and pressures. At 3 and 4 in., however, the burner was slightly noisy, and it was clear that with an air-gas ratio of about 2·4 : 1 the practical limit of primary aeration was approached for the burner and gas in use. Actually, there was very little change in illuminating power at 4 in. pressure when the air shutter was closed to correspond with the conditions of test for the plain nozzle; and the best illuminating power at the gas rate corresponding with 4 in. pressure would probably be obtained with a primary air-gas ratio lying somewhere between 2·08 and 2·47 for the pepper-box nozzle, when supplied with gas of the quality indicated. While the burner with the plain nozzle could not be started up from cold without back-firing to give a final air-gas ratio of 2·05 at 4 in. pressure with the hot burner, the pepper-box nozzle would permit of starting up from cold with the air shutter fully open, there being no tendency to back-fire at any stage as the burner approached its final working temperature.

Discharge of Gas Through Lighting Burner Nipples.

The work detailed in this section of the report was carried out as a preliminary to the aeration tests already described, and was intended, originally, to furnish some guide to the selection of nipples for those tests.

The discharge of gas through orifices of 0·25 in. dia. and upwards has been studied by many workers, and for ordinary gas-works pressures the relationship between discharge and pressure is fairly well established.

For the behaviour of very small orifices such as are used in multiple-orifice lighting-burner nipples, the work of Dr. J. S. G. Thomas may be consulted (Phil. Mag., Vol. XLVI, Nov., 1923), bearing in mind that the orifices used in his work were orifices in thin plates, and were prepared with extreme care.

The American Bureau of Standards has indicated some peculiarities in the behaviour of orifices of the sizes commonly used in domestic gas cookers, especially those due to differences in the shape of the nipple on the approach side of the orifice, and the thickness of wall through which the hole is made.

The single-orifice lighting-burner nipple is usually of a size intermediate between those studied by Dr. Thomas and by the Bureau, and it was considered desirable to establish the relation between discharge and pressure for such orifices, for town gas. It must be remembered that in commercial gas nipples the orifices rarely comply with the description of "holes in thin plates;" the thickness of wall usually being comparable with the diameter of the hole, and the shape of the nipple on the approach side of the orifice shows great differences, and is apparently a matter of taste with different manufacturers. Moreover, it was desirable to ascertain the characteristics of variable orifices fitted with regulating needles, such as were to be used in our aeration tests.

For this purpose a number of lighting-burner nipples were obtained of the type represented by Fig. 6. They were taken to pieces and subjected to examination with a hand lens, only those specimens which appeared satisfactory being retained. In most cases it was necessary to take off with an oilstone the burr left by drilling the orifice; to remove machine cuttings from the nipple; and to scrape off the burr left by drilling the holes in the regulating needle. Nothing was done to modify the size or shape of any parts, however, and these operations may be regarded merely as very careful finishing and assembly of the nipples. Careful cleaning, followed by examination and measurement of the orifice with a low-power microscope, preceded assembly.

In most of the nipples the clearance between the regulating needle and the body was large, bearing in mind the necessity for the accurate centring of the tip of the needle in a small orifice; and for fine regulation a more positive connection between the needle and the regulating spindle would seem desirable.

With each of fourteen selected nipples three series of tests were made at a number of selected gas pressures from 0 to 4·5 in. water gauge (w.g.).

(*i.*) With the regulating needle removed, so as to determine the behaviour of the simple orifice.
(*ii.*) With the needle in position, but drawn as far back as the mechanism of the nipple would allow, in order to obtain the maximum discharge.
(*iii.*) With the needle set so as to give a gas rate appropriate for the burner to which the nipple would be fitted.

The process of testing was simple, and it was mainly a question of careful observation of gas rates and corresponding pressures, and the application of a number of corrections in order to obtain gas rates of the requisite degree of precision for further calculation. Each nipple was mounted in turn above a fine-regulating quadrant-cock on the outlet of a $\frac{1}{10}$ c.ft. experimental meter; the gas pressure being measured immediately behind the nipple on a U-gauge filled with xylol. The gas was drawn from a 200 c.ft. holder, and its density was determined as indicated in Part II. of this report. By careful regulation of room temperature and the selection of suitable days for testing, it was possible to obtain atmospheric conditions not far removed from 60° Fahr. and 30 in. barometer, whereby large corrections to standard conditions could be avoided. A constant pressure of 5 in. w.g. was maintained at inlet meter, although the pressure at the nipple ranged from 1 to 4·5 in. It is not quite clear whether the volume and density of the gas should be considered with regard to the conditions prevailing on the pressure side of the orifice, or on the outlet side, although the difference in the two methods only exceeds the error of our experiments when the pressure exceeds 3 in. w.g. Actually all volumes and densities have been reduced to the prevailing atmospheric conditions (*i.e.*, zero w.g.) at outlet nipple.

The time required for a suitable number of whole revolutions of the meter was observed for each gas pressure, from which the gas rate was calculated. This was corrected for pressure at inlet meter (back to atmospheric), calibration error of meter, and variation in capacity of the meter per revolution, according to its rate of revolution (overdriving error), but *not* to 60° Fahr. and 30 in. bar., by means of the usual "tabular numbers." The barometric pressure and the temperature of the gas being known, it was possible to calculate the specific gravity of the moist gas under the prevailing conditions at the nipple, dry air at 60° Fahr. and 30 in. barometer being taken as standard (1·00).

The densities of the gases used in these tests rarely differed by more than 2 p.ct. from 0·475 (dry air = 1·00), and it was therefore a convenience to calculate, from the observed gas rate (corrected to the extent indicated above) and the density of the gas under the conditions at the nipple outlet, the corresponding discharge of gas of sp.gr.

0·475 (dry air at 60° Fahr. and 30 in. barometer = 1·00), assuming, for the purpose of calculating the correction, that the gas rate would be proportional to the square root of the density. The corrections to the observed gas rate to obtain the corresponding rates with gas of sp.gr. 0·475 were only small. Determinations were made at 1, 2, 3, and 4 in. water gauge (w.g.).

There was some difficulty in expressing concisely the results of the investigations. Graphical representation of the relationship between discharge and gas pressure was used; but there was room for considerable difference of opinion as to the position of the curve which best fitted the observations, and the method was abandoned as not sufficiently exact. Attempts were made to fit various curves to the observed points on the assumption that the discharge was proportional to the square root of the pressure, in turn making the curve fit at the highest pressure (4 to 4·5 in.), at 2·5 in. pressure (as being a typical working pressure), or at some other pressure which gave the best agreement between the square root curve and the observed points. It was evident that in the majority of cases it was not possible to fit any square-root curve to the observations without involving an error of more than 1 or 2 p.ct. of the gas rate, over some part or other of the pressure range 0·4·5 in. w.g. Numerous attempts to express the difference between observed and calculated discharges as a simple correction term to be applied to the square-root curve did not lead to any generally useful formula applicable to the whole of the nipples examined.

It was believed that the observations might be represented more accurately by an exponential formula of the type $q = Ap^B$, where q is the gas rate and p the pressure, A and B being constants, and the value of B not far removed from 0·5 (when $q = A\sqrt{p}$, or $Ap^{0.5}$). Logarithms were therefore taken of the pressures and corresponding gas rates, and by the usual mathematical methods the best-fitting straight line was calculated to pass through the points representing the observations with each nipple; and from the slope of this line the value of B was determined.

A formula of the above type, with the insertion of the appropriate values for the constants, gave a more accurate representation of the results over the whole pressure range than any of the square-root formulæ, although the relation found may be purely empirical. Even with this formula, however, the difference between observed and calculated values for discharge frequently exceeded 1 p.ct. over certain ranges; and the deviations were such as to suggest that the formula did not represent the best curve through the observed points (by method of derivation it was the best *simple exponential* curve), and that a more complex formula would be required. The matter was, however, not followed further.

In the Tables which follow, particulars are given as to the nipples used and the results obtained.

Nos. 1—6 and 7—11 are nominally all of one size.

In looking over the indices for the discharges from plain circular orifices (*i.e.*, nipples with needles removed), it will be observed that they range from 0·45 to 0·53. One would hesitate, however, to ascribe these variations to experimental error and take an average of the whole series, for it is evident that the low values for Nos. 6 and 7 could be repeated, as could the high value for No. 13. These indices are therefore characteristic of the nipples in question. Careful examination, however, failed to disclose any mechanical differences in the nipples which would satisfactorily account for the observed changes in the indices, and even greater variations may very well be expected in practice, when one remembers the care with which the above nipples were selected and prepared. There are in the table, however, comparatively few examples of indices greater than 0·5.

From columns 5 and 7 it would appear that the index is very little altered by insertion of the regulating needle into the orifice, although the figures in column 7 show, if anything, rather less variation than those in column 3, with a general average slightly below 0·5—say, 0·48.

The conclusions to be drawn from the figures below are that the relation between discharge and gas pressure for

Discharge of Gas through above Nipples.

Determined for gas of sp. gr. 0·475 at moment of discharge. (Dry air at 60° Fahr. and 30·0 in. barometer, = 1·00).

nipples of the above type may be represented approximately by a formula of the type $q = Ap^B$, but that the index B as well as the coefficient A will be different with different nipples, and will usually be slightly below 0·5. This must be taken into account in precise work, and will involve a determination of the characteristics of the particular nipple in which we may be interested, especially if aeration is in question.

On the other hand, for general work, and for calculating changes in gas rate and thermal delivery to be expected for changes in pressure of (say) 1 in. w.g. above and below a working pressure for which a discharge has actually been measured, the usual assumption that the discharge is proportional to the square root of the pressure will probably suffice.

The following table shows the percentage error involved in assuming that the discharge is proportional to the square root of the pressure, if it should actually follow some other index. The table is arranged for all indices to give the same result at 2·5 in. pressure.

These discharge tests were made as preliminaries to aeration tests with lighting burners. There is no reason whatever for associating a high degree of aeration with a high index in the above formulæ, or expecting any relation between the two.

It was fully realized that the equations given only represented the relation between discharge and gas pressure. It might very well happen that a nipple would discharge its

Pressure and Gas Discharge.

Percentage correction to discharge rate calculated on basis of square root of pressure, if the true index of the exponential formula $q = Ap^n$ is that given at the head of each column. Agreement is made exact at 2·5 ins. w.g. for all indices, and the heavy line encloses all values for which the error is less than 1 p.ct.

gas in a rough and turbulent manner not favourable for highly efficient injection, or that the position of the gas stream as regards centring in the mixing tube or inclination to its axis might be at fault. There are independent sources of variation in the behaviour of injectors upon which discharge-pressure relations can furnish no information, and experimental determination of the degree of aeration is essential.

PART II.

SPECIFIC GRAVITY OF GASES.

In connection with the investigation of the aeration of burners, and the discharge of gases through orifices, it has been desirable to know with some accuracy the specific gravity of the gas being used. An error not greater than ±0·5 p.ct. was aimed at, or for a typical town gas (say) ±2 in the third decimal place of the density figure. This section of the report will be divided into three parts, as follows:

1. A description of the instruments used for the determination of specific gravity.
2. Details of the methods used.
3. A comparison of a number of specific gravity determinations by different methods.

1.—Instruments for Determination of Specific Gravity of Gas by Differential Column Method.

The determination is made by measuring the difference in the pressure exerted by a column of gas and a similar column of air, from which data the specific gravity can be calculated as will be shown later. The method has been known for a number of years (*e.g.*, see Threlfall, Proc. Roy. Soc. A. 77, 1906), but was revived and a convenient arrangement of apparatus described by Blackie in 1922 ("An Apparatus for the Measurement of the Specific Gravity of Gases in Small Quantities," Alfred Blackie, M.A.; Fuel Research Board, Technical Paper No. 5). Preliminary tests had been made and the applicability of the method to the requirements of our research was under examination when the 11th Report of the Gas Investigation Committee was presented last year (see pp. 26 and 33, 11th Report, 1924). The description which follows is that of the apparatus and procedure which we have since developed and found to yield satisfactory results. In the main it follows the paper already referred to, but with amplification of the working details.

Gas and Air Columns.

The gas and air columns were contained in copper tubes of ½ in. bore, surrounded by a water-jacket built up of 1½ in. iron piping as shown in fig. 20. The tubes are each about 20 ft. long, this giving a pressure difference which can be measured with a degree of accuracy comparable with that of the other measurements involved. As it was not possible to find accommodation for an apparatus of this height inside the laboratory, it was secured to the outer face of the laboratory wall near a window, the window-ledge forming a convenient foundation for the pressure gauge. Each tube terminates in a cylindrical box 1½ in. dia. by 1½ in. deep, provided with a diaphragm perforated with a ⅛ in. hole, and a similar hole in the base. These boxes are used to minimize the effects of diffusion of air into the tubes while a test is in progress, and the bases of the two boxes should be at the same level with the outlet apertures close together. With this arrangement the sensitive pressure gauge sometimes showed oscillations which made it impossible to obtain reliable readings; this was probably due to mutual screening of one box by the other when the wind was in certain directions, and to eddies set up near the water jacket. The boxes were therefore enclosed in an outer chamber with a single perforation in its base, this being covered with a loosely fitting baffle plate. With this arrangement sufficiently steady readings have been obtained even in windy weather. A third copper tube was also fitted into the jacket to act as the bulb of an air-thermometer, as described by Blackie; but in addition a thermometer pocket of the usual type was provided where the water entered the base of the jacket. This was fitted with a mercury thermometer graduated

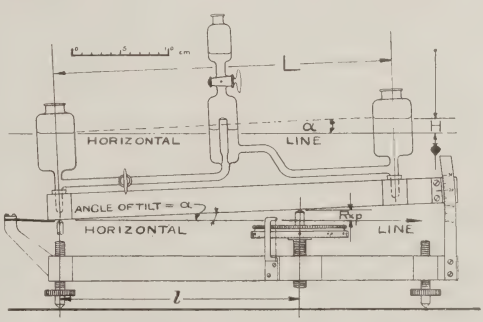

Fig. 18.—Outline diagram Chattock Gauge

in tenths of a degree Centigrade. With a good flow of water through the apparatus there was very little difference between the temperature of the water entering the jacket and that overflowing from the top—the excess rarely being greater than 0·5° C. The greatest error thus introduced is under-estimation of the mean temperature of the tubes by 0·25° C. Perforated distance pieces were provided for the tubes about every 18 in., the perforations being ½ in. holes alternately at the centre and near the circumference of successive spacers.

Chattock Tilting Gauge.

The instrument used for measuring the pressure difference between the columns was a tilting manometer of the Chattock type made to our designs by Messrs. Scientific and Projections, Ltd., the novel features of which were described and illustrated in the 11th Report of the Gas Investigation Committee (p. 25). Fig. 18 shows the essentials of the instrument.

As the result of continued experience in the use of the gauge, further improvements have been effected. Control of the illumination of the instrument is very important if consistent readings are to be obtained. This is now effected by enclosing the gauge in a case to exclude most of the extraneous light. The source of illumination is an ordinary pocket flash lamp bulb perma-

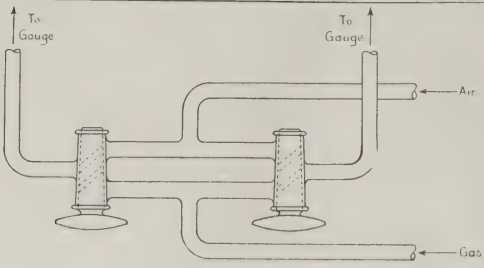

Fig. 19.—Change-over Cock System for Chattock Gauge.

nently fixed to the tilting member some 3 in. above the rear pivot, the light being directed as required by the mirror behind the centre vessel. Suitable wiring and a switch are provided. A black-paper collar encircles the upper part of the centre vessel and is adjusted by trial to cut off most of the light above the meniscus. The silhouette of the meniscus shows a very clearly defined line in the field of the microscope for setting, and, if the gauge is moved from place to place, trifling readjustment of the mirror is usually all that is required to reproduce the former conditions of illumination. The heating-up of the apparatus with such a source of light is negligible. The reading microscope is furnished with a Watson 1 in. parachromatic objective and a 6x eyepiece. This, with the usual microscope body-length, represents about as large a magnification as it is convenient to use, and only leaves about 1 mm. working distance between the objective and the walls of the centre vessel. A single silk fibre provides a suitable line in the eye-piece. Through the

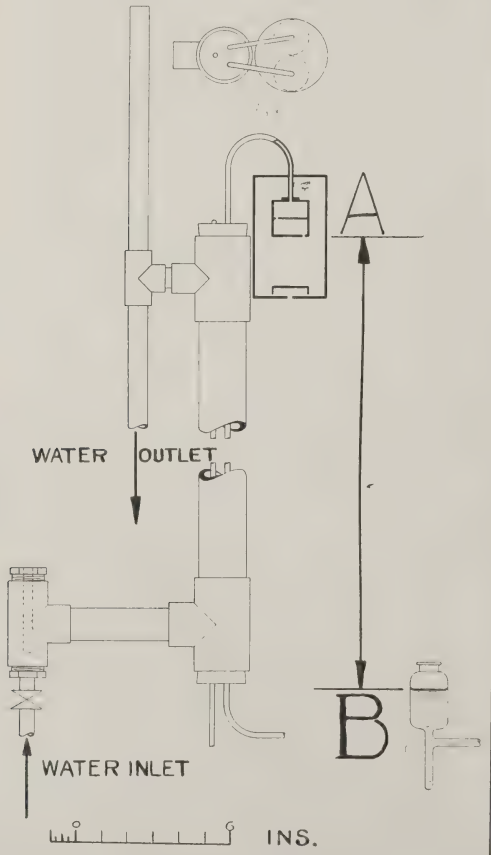

Fig. 20.—Water-Jacketed Gas and Air Tubes.

kindness of Dr. H. Hartley, our attention was called to a critical report upon a number of sensitive gauges used in the Aerodynamics Laboratory at the University of Toronto (School of Engineering Research University of Toronto, Bulletin No. 2, "Aerodynamic Papers," J. H. Parkin, 1921). As a result of this communication, it was decided to replace the castor-oil salt solution combination originally used in the gauge by one of "Nujol" and distilled water. "Nujol" is a proprietary brand of medicinal paraffin which we found to have a viscosity only about one-tenth that of castor oil; and it is immiscible with water. The density of the sample in use is 0·883 at 60° Fahr., changing with temperature at the rate of 0·00035 per °Fahr. The meniscus at the junction of the "Nujol" and water remains well-defined and free from scum over long periods, and accurate settings of the gauge are therefore facilitated. The use of a gauge liquid like distilled water, with well-known physical properties, also has much to commend it. Trouble was experienced at first owing to the solution of tap-grease by the "Nujol." The latter alone was, however, found to be a suitable lubricant for well-ground taps if these were not pressed too heavily into their seats, the taps turning with very little effort, and so causing the minimum disturbance of the gauge.

In our original gauge an attempt was made to secure sensitivity by making the innermost tube of small diameter—3 m.m. internal. The gauge responded quickly to small pressure changes, but the movement of the meniscus for a given tilt of the gauge was, contrary to expectations, small and irregular. This is to be associated with surface-tension phenomena. In the latest instrument, the bore of the inner tube has been increased to 9 m.m., and a meniscus height of 2 to 3 m.m. is used. Under these conditions, settings can be repeated easily to within ± 0·2 divisions of the micrometer head—*i.e.*, to ± 0·003 m.m. w.g.—and the time required for the gauge to take up its final reading is less than 15 seconds.*

At a convenient place in front of the gauge a wooden block has been secured to the bottom of the case. This carries two two-way cocks sealed together as indicated diagrammatically in fig. 19, connections being made permanently between these and the gauge by short flexible pieces of rubber tubing. It will be seen that this arrangement allows the gauge to be isolated; either limb can be supplied very expeditiously with gas or air at will, and both limbs can be subjected to the same pressure or to atmospheric pressure. Further, as connections are made from other apparatus to this cock system and not directly to the gauge, there is no risk of disturbing the adjustments of the latter while re-arranging connections, or by an accidental pull on the connecting tubes.

We have found that, when subjected to a rising temperature, the gauge exhibits a drift of zero which is by no means negligible. The amount of drift for a given change in temperature will depend upon the dimensions of the gauge, the nature and quantities of the liquids used for filling, and to some extent upon its initial temperature. A precise value cannot therefore be given. Experiments specially conducted for the purpose show, however, that for our manometer the drift is of the order of 2 micrometer divisions per °Fahr. change in temperature of the instrument. It is thus important that the temperature of the instrument should be kept constant during observations, or that the temperature should change slowly and steadily, so that an attached thermometer may indicate the temperature of the gauge with reasonable accuracy. A thermometer has been fitted to the gauge and surrounded by a water jacket which is made approximately of the same dimensions as the central vessel by the side of which it is mounted. It is not intended that the figure previously given for zero drift (2 divisions per ° Fahr.) should be used for the calculation of corrections. It is preferable that frequent zero checks should be made, together with temperature observations. The correction to intermediate readings can then be made in accordance with temperature readings made at corresponding times. It would be

* One revolution = 100 divisions on head = 1 m.m. lift on screw (approx.) = 1·4 m.m. w.g. difference in pressure.

2·7915 = Mean pull of gas column expressed in turns micrometer head.

2·7915 × 1·422 = 3·969 = Vertical displacement of water surfaces in m.m.

3·969 = Equivalent in m.m. w.g. at 4° C.

$$6221 \times 0\cdot001293 \times \frac{273}{278\cdot5} \times \frac{29\cdot65}{29\cdot92} = 73\cdot394 \times \frac{29\cdot65}{278\cdot5}$$

= 7·814 = Pressure due to air column under the same temp. and pressure conditions as in the gas colum (m.m. w.g.)

Then specific gravity of gas*

$$= 1 - \frac{3\cdot969}{7\cdot814} = 1 - 0\cdot5079$$

$$= 0\cdot4921.$$

* Wt. of 1 c.ft. of dry gas. / Wt. of 1 c.ft. of dry air. under the same conditions of temp. and press.

possible by suitable alteration of the relative sizes of the central and one of the outer vessels greatly to reduce this zero drift, but exact compensation could not be expected over a wide range of working temperatures. In addition to correction for zero drift, any considerable change in temperature will entail a correction for change in density of the water in the gauge. This may be obtained from tables (*e.g.*, Kaye and Laby's "Physical and Chemical Constants, 1918," p. 22), although the change may be neglected between 0° and 20° C., unless the pressure is required to a greater degree of accuracy than ± 0·2 p.ct.

The pressure exerted by a column of typical town gas of specific gravity 0·5 and length 20 ft. will be slightly under 4 m.m. w.g. For a determination of specific gravity to within ± 0·5 p.ct. it can be shown that this pressure must be known to within ± 0·02 m.m. w.g. Actually the pressure is obtained from the difference of two readings, each of which must therefore be known to within ± 0·01 m.m. w.g., *i.e.*, to within ± 0·7 divisions on the micrometer head. This, it should be emphasized, is the accuracy with which the absolute magnitude of the whole pressure reading should be known, and is distinct from the smallest *variation* in pressure which can be definitely measured on the gauge, previously given as ± 0·2 micrometer divisions. Very careful standardization and calibration of the gauge are therefore demanded in order to obtain pressure readings correct within the above limits. A description of the details of the calibration would be unduly lengthy, but it consisted essentially in mounting a mirror on the tilting member, and treating the system as an optical lever; the tilt for various micrometer settings being determined to about ± 1 second of arc, or ± 0·15 micrometer divisions. It may be mentioned that for several months the gas densities obtained by the use of this gauge were systematically higher by about 1 p.ct. than those obtained by other methods, this difference being about double the estimated experimental error. As a result of our calibration, the tilt of the gauge was found to correspond with a mean micrometer pitch of 1·0108 m.m., whereas we had previously assumed that the pitch of the screw was in accordance with our specification—viz., 1·00 m.m. Upon re-calculating the densities with the revised figure for the screw-pitch, the various methods gave results in good agreement with one another.

The gauge thus developed can hardly be regarded as portable in the ordinary sense of the word, but it may nevertheless find additional applications in the gas industry when it may be necessary to measure small pressure differences with precision. Among these may be mentioned pressures in burners, flue draughts exerted by gas appliances, ventilator suctions and pressures, Pitôt tube measurements, and the standardization of other types of sensitive gauges.

2.—Method of Making Specific Gravity Determination.

The water flow is established through the jacket surrounding the differential columns; the Chattock gauge is set up and adjusted by its longitudinal and cross levels; and the microscope set so that the image of the meniscus is approximately on the cross-wire. Between the gauge and the differential columns, two straight tubes about 10 in. long and ⅜ in. dia., filled with calcium chloride, are placed horizontally and on a level with the surfaces of the water in the gauge. These serve to dry the gases entering the columns, and will remain effective for a considerable number of determinations. The control cock on the horizontal limb of the gauge is closed, and air is forced through the space in each end vessel and drying tube into the corresponding differential column. The air is conveniently supplied from an aspirator bottle; and about 2 litres through each tube, taking 3 to 5 minutes, is usually sufficient before determining the first zero reading of the gauge. The two taps permitting the air-flow are closed, and with one hand on the micrometer head the observer cautiously opens the control cock on the gauge, care being taken to keep the image of the meniscus near the line in the microscope eye-piece by manipulation of the micrometer head. The meniscus is then set as closely to the line as possible, and a reading on the micrometer head is taken. With the cock still fully open, the micrometer head is moved some 5 divisions, after which the meniscus is re-set to the cross line and the micrometer head is again read. A third setting and reading are made, and the temperature of the instrument is noted. The mean of the three readings constitutes the "first zero reading." The control cock on the gauge is next closed, and the gas which is to be exam-

ined is passed through one tube only, for 3 to 5 minutes. It will be found that the small copper tubes present a considerable resistance to the flow of the gas; and with an available pressure of about 5 in. w.g., gas will pass through the system at the approximate rate of only 1·7 c.ft. per hour, *i.e.*, about 2 to 3 litres of gas will be used. This is no disadvantage, however, as the drying of the gas by calcium chloride might not be satisfactory at greater speeds. During the last minute of this period, air should be passed through the other column. The gas and air are shut off, and three micrometer settings, together with a temperature reading of the instrument, are taken as in the case of air. The mean gives the " first gas reading." At the same time the temperature of the differential columns should be noted to 1/10°C., and the barometric height should be observed. If an approximate sp. gr. only is required, these two sets of readings will furnish the necessary data.

It is our practice, however, to close the control cock on the gauge and repeat the passage of gas for a further 3 minutes, and obtain a " second mean gas reading " from three settings in the same way. This is a safeguard against a faulty micrometer setting in the first test, or inadequate clearing of the gas tube from air. The control cock is closed, and both limbs are then swept with air for a further 3 minutes, thus restoring the apparatus to its original state; and from three settings a " second mean zero reading " is obtained, together with the corresponding temperature. Assuming that the meniscus has not been subjected to any violent displacement, the difference in the two zero readings indicates the extent of the zero drift. If, through faulty manipulation, the meniscus should be seriously disturbed, it is better to wait a few moments for the instrument to settle, and reject any difference figure obtained from values including the period of such disturbance. The calculation of the result is best illustrated by a worked example.

From the foregoing description the upper part of the table should be quite clear. The second correction—correction for screw error—is obtained from calibration data, and converts the micrometer reading into the equivalent reading on a perfect screw of the same effective mean pitch as that of the screw in use. The temperature corrections are obtained by comparison of the thermometers used with an N.P.L.–standardized thermometer. The barometric height should be accurate to 0·05 in. at least, so that the observed height must be reduced to standard conditions. The principal correction will be the temperature correction (for English barometers, mercury to 32° Fahr., brass scale to 62° Fahr.), usually involving a deduction of about 0·07 to 0·10 in. from the observed height. The factor 1·422, by which the mean micrometer difference is multiplied, is known as the " constant of the gauge." It is derived from careful determination of the dimensions indicated on fig. 18.

L = distance between the centres of the water surfaces in the outer vessels.
l = distance between line joining fixed pivots and axis of micrometer screw.
p = effective mean pitch of screw.
R_1 = first micrometer reading.
R_2 = second " "
$R = (R_2 - R_1)$ = turns of micrometer screw.
H = lift of water surface in right-hand vessel above that in left-hand vessel.
D = sp. gr. of liquid filling gauge (water at 4° C. = 1·00). The water and not the " Nujol " must be considered here.
α = tilt of gauge from horizontal.

Then pressure indicated by gauge
$= HD = LD \sin \alpha = LD \tan \alpha \cos \alpha$.
But if α is small, say less than 2°, we may write without significant error,
$= LD \tan \alpha = LD\ R_1 \frac{p}{l}$.
The pressure is obtained as a difference of two readings, thus—
$$P = L.D\,(R_2 - R_1)\,\frac{p}{l}.$$

$L.D\ \frac{p}{l}$ is a constant for any particular instrument, and is the " constant of the gauge." Had the temperature of the instrument been 15° C., for example, instead of 9·7° C., the density of the water would have been only 0·999, and consequently the value 3·969 would have been reduced to 3·965 in the second entry, to obtain the pull in m.m. of water of standard density. For 9·7° C. the correction is only 2 parts in 10,000, and is consequently negligible.

The next line in the table is a calculation of the pressure exerted by a column of air at the same temperature and pressure as the gas and of the same height. The height in question is that marked AB in fig. 20, and must be measured vertically and known to within a few millimetres. Where the apparatus is installed in a permanent position, it is convenient to measure once for all the height from the base of the diffusion boxes to the surface of the slab carrying the gauge. The distance from the slab to the mean height of the surfaces of liquid in the gauge is then deducted. This may differ slightly from time to time according to the filling and adjustment of the gauge, and is more easily checked than the whole height. In our apparatus as at present installed, the distance is 6221 m.m. (= 20 ft. 5 in. approx.).

0·001293 is the weight in grammes per c.c. of pure dry CO_2—free air at 0° C. and 760 m.m. pressure; 273 is the absolute temperature corresponding to 0° C., and 278·5, that corresponding to 5·5° C., the temperature of the columns; 29·65 is the corrected observed barometric height, and 29·92 the equivalent in inches of 760 m.m.

It is clear that for a particular installation a number of these factors will be constant, so that the arithmetical work in practice is much shorter than in this example. Thus, for our apparatus, the expression for the pressure due to the air column reduces to $73{\cdot}39\ \frac{B}{T}$ m.m. w.g. where B and T are the barometric height and absolute temperature of the gas column respectively.* If the weight of the water column indicated by the gauge is deducted from the calculated weight of the air column, the difference must be that of the gas column, since the apparatus is in equilibrium. The ratio of the weight of the gas column to that of the air column (or their equivalents in m.m. w.g.) gives the sp. gr. of the gas. A slight re-arrangement of the data gives an expression which can be calculated with less labour, viz. :—

$$\text{Sp. gr.} = \frac{\text{wt. of gas column.}}{\text{wt. of air column.}} = \left[1 - \frac{\text{wt. of water column.}}{\text{wt. of air column.}}\right]$$

The accuracy of the determination will be indicated later (section 3 below) when comparing the specific gravity values obtained by different methods for a number of gas samples.

It has been pointed out that the gauge reading may be doubled by modifying the procedure, and passing gas and air alternately through the right and left hand differential tubes. While this is true, it may require an inconveniently large tilt on the gauge, a correction for zero drift cannot be applied with the same certainty, and the gauge liquid is likely to become contaminated with gas to a serious extent if not swept with air from time to time. Sufficiently accurate readings can be obtained with 20 ft. tubes without adopting this plan.

3.—Comparison of Specific Gravity Determinations by Different Methods.

In the table which follows, a number of comparative specific gravity determinations are given covering a period of several months, these having been made in the course of other experiments. Samples of gas mixtures were taken simultaneously, and the determinations were made by alternative methods selected from the following :—

(i) *By the differential column method* already described.

(ii) *By gas analysis.* For this purpose the analysis was made as carefully as possible, each constituent was calculated to the second decimal place, corrected as indicated in Appendix I., and then rounded to the nearest 0·1 p.ct. C_mH_n was assumed to have a density 1·3 (air=1).

(iii) *By weighing* the carefully dried gas in sealed bulbs of about 290 c.c. capacity.

It was originally intended that this should form the standard with which the other methods might be com-

* $(6221 \times 0{\cdot}001293 \times \frac{273}{29{\cdot}92} \times \frac{B}{T} = 73{\cdot}39\ \frac{B}{T}$ m.m. w.g.)

pared. The tests occupied much time and were executed with every care and precaution. Reviewing the whole of the conditions, however, and the limitations of the instruments available, it is doubtful whether we should be justified in ascribing to these figures a greater precision than ± 0·002, although it is possible that they are correct to ± 0·001.

A few further tests have been made with an effusimeter; but there seems to be no ground for altering the opinion of this instrument already expressed in the 11th Report (p. 33)—namely, that while it will on most occasions yield results which are comparative, or even close to the correct result, it is liable to be erratic in its behaviour, and consequently cannot be relied upon for any but the roughest estimations of specific gravity.

Comparative Specific Gravity Determinations.

1.	2.	3.	4.	5.	6.
Differential Columns.	Weighing.	Analysis.	1–2.	1–3.	3–2.
·4855	·4925	..	−0·0070	..	..
·4856	·4916	..	−0·0060	..	..
·4846	..	·4903	..	−0·0057	..
·4922	·4911	·4914	+0 0011	+0·0008	+0·0003
·4852	·4874	·4848	−0·0022	+0 0004	−0·0026
·4769	..	·4768	..	+0·0001	..
·4800	..	·4816	..	−0·0016	..
·4921	·4963	..	−0·0042	..	..
·5002	..	·5000	..	+0·0002	..
Mean . .	..	..	−0·004	−0·001	−0·001

Each horizontal line in the above table refers to an independent gas sample. There is, therefore, no point in averaging columns 1, 2 and 3 respectively. In every case no importance attaches to the fourth figure in the values given; they are merely retained to prevent an accumulated error due to rounding-off at too early a stage.

The specific gravities by analysis are probably not in error by more than ± 0·002. With one exception, the specific gravity by the differential column apparatus and by analysis (column 5) agree within these limits, there being a tendency for the differential column method to yield slightly low results. On only two occasions have determinations been made by weighing and analysis on the same gas sample, and the comparisons show the specific gravity determinations to be in satisfactory agreement (column 6), weighing yielding, if anything, a slightly higher value. The probable error of the weighing method has been estimated above at ± 0·001 to ± 0·002. The mean difference between weighing and differential columns (column 4) is only 0·004, or about 0·8 p.ct. on gas of sp. gr. 0·49. The first two values in column 4, however, refer to determinations made at a comparatively early date when the technique of the method was not fully developed. It is probable, therefore, that 0·002 or 0·003 more nearly represents the mean difference in the two methods, while, if allowance is made for the difference between the results by analysis and by weighing, the mean discrepancy would be only 0·001 or 0·002. The differential column method is liable to certain small errors (*e.g.*, diffusion of gas and air into end boxes; removal of CO_2 by gauge water; unequal lengths of gas and air columns as gauge tilts; underestimation of temperature of columns), difficult to determine individually, but collectively amounting to the equivalent of 0·001 or 0·002 on the specific gravity, and usually acting in the direction of giving a low value. Bearing this in mind, the three methods may be regarded as yielding results in excellent agreement, usually within 0·002, although the discrepancy may occasionally reach 0·005—*i.e.*, 1 p.ct. on a typical town gas of sp. gr. 0·5.

Summarizing.

The weighing method cannot be regarded as suitable for technical work, and in practice is not likely to be more accurate than the other methods.

An accurate gas analysis will allow the specific gravity to be calculated to within ± 0·002, but an analysis of the requisite precision cannot be executed in less than one hour, even by a skilled operator.

The differential column apparatus provides a means whereby the specific gravity can be conveniently determined within ± 0·002 of its true value, and in a comparatively short time (say, 20 minutes). Our experience with the apparatus is thus in general agreement with that of the Fuel Research Board, as indicated in its Technical Paper No. 5.

Note on Definition of Specific Gravity of Gas.

If it is desired to express the specific gravity of a gas to 1 p.ct. or more closely, careful definition of the property in question is necessary. The specific gravity is usually defined as the ratio of the weight of 1 c.ft. of gas to that of an equal volume of air at the same temperature and pressure.

All our specific gravity values are quoted for dry gas compared with dry air; and the value so obtained is practically independent of the choice of any particular temperature and pressure, so long as these are the same both for gas and for air.

In practice, gas carries a certain amount of water vapour, frequently being fully saturated. The specific gravity is therefore sometimes defined as the ratio of the weight of 1 c.ft. of gas to that of 1 c.ft. of air at the same temperature and pressure, both being saturated with water vapour. This ratio, however, is not a constant, altering appreciably with temperature, and somewhat less so with the usual changes in barometric pressure; the effects being more marked the further the density of the gas departs from that of air. It is on account of this variation that the difficulty is not removed by specifying a standard temperature, pressure, and saturation—*e.g.*, 60° Fahr., 30 in. pressure, and full saturation for both gas and air, a point which is sometimes overlooked.

Effusimeters usually work with water as the confining liquid, both gas and air therefore being moist. The specific gravity obtained with such an instrument for a particular gas will therefore not be the same, even when the effusimeter is working satisfactorily, as by the three methods given in this report. The order of the difference is indicated below, and is about 1 to 1½ p.ct. for ordinary town gas.

Sp. Gr. of Gas on Basis $\frac{\text{Dry Gas}}{\text{Dry Air}}$ (Taking Dry Air = 1·00.)	Sp. Gr. of Gas on Basis $\frac{\text{Sat. Gas}}{\text{Sat. Air}}$ (Taking Sat. Air at 60° F. and 30 In. = 1·00.)	Sp. Gr. of Gas on Basis $\frac{\text{Sat. Gas at 60° F. 30 In.}}{\text{Dry Air at 60° F. 30 In.}}$
0·400	0·406	0·404
0·500	0·505	0·502
0·600	0·604	0·600

Given the dry gas value, which is a constant, it is $\frac{\text{dry gas}}{\text{dry air}}$ of course always possible to calculate the true density of the gas for any specified temperature, pressure, or degree of saturation.

It will be seen from column 3 of the table above that for ordinary town gas under average atmospheric conditions in this country, the specific gravity of the gas as frequently used (namely, moist) compared with dry air, differs but slightly from that of the dry gas compared with dry air. The use of dry air as the basis of comparison also has the convenience that data for the weight per c.ft. of dry air under various conditions of temperature and pressure can be obtained from tables, or may be very easily calculated.

APPENDIX I.

Notes on Precise Gas Analysis.

In our aeration and other investigations accurate gas analyses have been of vital importance. The following critical review of the methods of analysis we have employed may, therefore, be of interest. The notes apply to analyses conducted in a Bone-Wheeler apparatus of the usual dimensions (graduated length of pressure limb 600 m.m., capacity of burette to "constant volume" mark 75 c.c.), and assume an original gas pressure of about 500 m.m. mercury. All combustions were made

over copper oxide in a silica tube. The chief advantages of this method of combustion are that a much larger volume of gas can be burned than by explosion, thus giving greater accuracy in measurement; combustion can be extended over sufficient time to secure completion; there is no careful adjustment necessary to secure the right composition of an explosive mixture; no auxiliary supply or analyses of oxygen are required. The feature which distinguishes this process from those of other workers using copper oxide combustion lies in the evacuation of the combustion tube before and after combustion, using the gas burette as a mercury pump.

After critical examination, the method was extensively used by us for the determination of nitrogen, and was first reported upon, briefly but favourably, by Mr. James W. Wood in the First Report of the Gas Investigation Committee (1918, p. 76); no details, however, being there given. The apparatus was described at a later date by Dr. E. W. Smith, to whom we were indebted for the essentials of the process before publication ("Gas World," 1919, Vol. 71, p. 342), and was again described and illustrated by Dr. Parker in the 4th Report of the Gas Investigation Committee (pp. 316-317).

For the purposes of the present inquiry an attempt has been made to conduct gas analyses in which each constituent should be determined to within ± 0·05 p.ct., the final results being returned to the nearest 0·1 p.ct. To do this without making a number of analyses and averaging the results calls for very precise working, and certain systematic errors must be carefully eliminated.

There is no difficulty in reading the gas burette to ± 0·1 mm., *i.e.*, to ± 0·02 p.ct. on the gas volume; but even if a temperature correction is applied (and temperature variation is the commonest source of erratic results), this does *not* represent the precision of the analysis.

In 1918, 1919, and 1920, we were making very frequent determinations of nitrogen by combustion of the *whole* of the gas over copper oxide, and measurement of the residual nitrogen using this apparatus. Even at this early date it was observed that the nitrogen figure so obtained was consistently 0·3 to 0·5 p.ct. lower than when the nitrogen was similarly determined at the end of a complete analysis involving absorption of CO_2, hydrocarbons, O_2, and CO in the usual way, before combustion. Such accumulation of nitrogen was attributed to air or nitrogen dissolved in the reagents (evidence of the freedom of the apparatus from leaks being satisfactory), and an attempt was made to remove this by placing the reagents in communication with an evacuated vessel immediately before use. For obvious reasons this treatment cannot be applied either to bromine water or ammoniacal cuprous chloride solution.

Some reduction in the nitrogen discrepancy was effected, but the process was abandoned, as it complicated the analysis and introduced certain other small errors. Since 1918 the methods of manipulation have been improved, and the amounts of reagent have been reduced to the minimum compatible with satisfactory and reliable absorption. Nevertheless, the "direct" nitrogen is still always slightly less than the nitrogen residue at the end of a complete analysis; the discrepancy being remarkably constant, and usually lying between 0·2 and 0·3 p.ct., when a prescribed routine is followed. This amount should certainly be deducted from the nitrogen figure and added to the values for the absorbable constituents, but its distribution is open to discussion. In the absence of precise information on the point, it has been our custom to divide the discrepancy among the absorbable constituents, in proportion to the volume of reagent used for each—thus, CO_2: C_mH_n: O_2: CO., 1: 3: 2: 4. The most important correction is the addition of nearly 0·1 p.ct. to the unsaturated hydrocarbons, having regard to its effect upon C.V. and air requirement.

In certain analyses we were surprised to find small amounts of oxygen where complete absence of oxygen was expected. It was then found, by carrying out all the operations of a complete analysis with a sample of pure nitrogen or hydrogen, that if the bromine water was more than a few hours old, and had been exposed to light, there was an evolution of gas equal to 0·10 to 0·20 p.ct. of the gas taken—presumably oxygen, since it could afterwards be absorbed by pyro. Such evolution would seriously reduce the percentage of unsaturated hydrocarbons obtained by the analysis, and would give misleading figures for oxygen content in the next absorption (O_2), especially when controlling the small amounts of excess oxygen in purified gas, where revivification *in situ* is practised. This difficulty has been overcome by preparation of the bromine solution in small quantities immediately before use.

Upon a number of occasions the combustion after the removal of CO has been conducted in two stages—(i) at a barely perceptible red heat, (ii) at a bright red heat—with suitable pumping and measurement after each stage. Hydrogen burns quite readily over copper oxide at a dull red heat, and the contraction in volume is a direct measure of the amount of hydrogen present. After the second combustion at a higher temperature, there is usually an increase in volume, as might be expected if paraffin hydrocarbons higher in the series than methane (CH_4) were present. This determination has been made repeatedly; and the gas produced by steaming in the vertical retort installations at Meadow Lane, Leeds, for example, usually contains about 1·3 to 1·5 p.ct. of such hydrocarbons expressed as ethane (C_2H_6).

Ordinarily, the combustion is carried out in one stage, and the whole of the CO_2 produced is calculated as methane. The hydrogen is, therefore, under-estimated to the extent of the volume of C_2H_6 present. This is of no great consequence, however, for it can easily be shown that the density and air requirement of the gas calculated from the conventional analysis (*i.e.*, expressing the whole of the paraffin hydrocarbons as CH_4) gives precisely the same result as that where H_2, CH_4, and C_2H_6 are given separately, while the calorific value calculated from the conventional analysis is slightly too low to the extent of 0·7 B.Th.U. per c.ft. for each 1 p.ct. of ethane present.

At a temperature adequate for the combustion of methane there is a copious evolution of oxygen from the combustion tube, so that any instruction to carry on the pumping of the tube until a vacuum of, say, 0·5 m.m. is attained, is useless. Such oxygen would give too high a value to the nitrogen, and a correspondingly low value to the hydrogen figure in a one-stage combustion, the error often reaching 5 p.ct. There are two ways of dealing with this matter. The first is to follow the final CO_2 absorption with pyro, deducting the oxygen found from the nitrogen, and adding it to the hydrogen. An alternative plan due to Dr. Parker is to complete the combustion and then extinguish the burner heating the tube, continuing, however, to pass the gas backwards and forwards through the tube until it falls below a dull red heat. This usually takes about 3 minutes, and the oxygen is re-absorbed practically quantitatively. The tube is then pumped off as usual. This latter scheme is admirable except when gases are being treated in rapid succession for determination of nitrogen only, when it is perhaps more convenient to keep the tube hot and absorb the oxygen and CO_2 together, with alkaline pyro, before measuring the nitrogen.

Another irregularity of the copper oxide combustion gave some trouble in making precise determinations of air-gas ratios for burner mixtures, which, it will be recalled, depend upon accurate determinations of the CO_2 produced per cubic foot of the gas in use and of the mixture formed respectively. Analyses were always made in duplicate, and it was observed that, whenever a freshly oxidized combustion tube was used, or whenever a CO_2-in-mixture determination preceded a determination of the CO_2 produced per c.ft. of gas, the CO_2 obtained was lower than in the confirmatory analysis which followed on another portion of the same gas sample. The discrepancy was of the order of 0·3 p.ct., and was therefore too serious to neglect. It will be realized that the residual atmosphere at the end of an analysis of a town gas containing 20 p.ct. of methane and 10 p.ct. of nitrogen will consist of 66 p.ct. by volume of CO_2; while that from the combustion of the original gas, no constituents having been absorbed, will contain over 80 p.ct. of CO_2. The gas burette

and its connections are kept moist in the first place, and there is, in addition, the water which is produced by the combustion of the hydrogen and hydrocarbons of the gas. These conditions must of necessity favour the retention of a certain amount of CO_2, despite the reduced pressure in the apparatus at this stage, and it is surprising that the amount retained is so small. If the CO_2 is absorbed and the CO_2–free residue (augmented by nitrogen or air if necessary to give an amount convenient to manipulate) is re-circulated through the combustion system and pumped off again, an amount of CO_2 will be recovered upon absorption with potash which corresponds closely, but not exactly, with the CO_2 discrepancy in the consecutive analyses. Such "recovered" CO_2 should plainly be added to the larger amount already determined. It is not clear whether any corresponding correction should be made to the H_2, CH_4, and N_2 in a complete gas analysis, however, and on what basis. This will depend upon whether the CO_2 is dissolved or is present as gas in the combustion tube and its connections when the earlier measurements are made. When, as in practice, a number of analyses of gases of approximately the same character follow one another, the amount of CO_2 retained in the apparatus is approximately constant, so that the error would only appear on the first of the series. Even this might be avoided by a preliminary blank or "conditioning" combustion, no measurements, of course, being necessary. Where, as in our air-gas ratio determinations, however, gases giving widely different CO_2-concentrations in the residue after combustion follow one another, this plan cannot be followed, and it has proved necessary frequently to determine this small amount of "recovered" CO_2 and employ an appropriate correction. The same considerations would apply, with modifications, to analyses conducted by explosion, and are not peculiar to combustion over copper oxide.

It is not possible to calculate the specific gravity of a town gas from an analysis without knowing something of the nature, as well as the quantity, of the unsaturated hydrocarbons. In our analyses no attempt has been made to separate or identify these by the use of several reagents of different chemical composition or strengths. Instead, however, an attempt has been made to determine their combined effective molecular weight, and hence their density. To do this, two partial analyses have been conducted. First, a direct combustion is made of a portion of the gas sample with a determination of the total CO_2, present and produced. Secondly, another portion of the sample is taken, the CO_2 present is determined, hydrocarbons are removed, and the residue is then completely burned. It is thus possible to determine the sum of the CO_2 present and that produced from all constituents except the hydrocarbons. The difference in the total CO_2 produced in the two determinations is that due to the combustion of the unsaturated hydrocarbons. Now one volume of C_mH_n yields $_m$ volumes of CO_2. From the above data, therefore, $_m$ is readily determined. This method does not give a value for $_n$, but it will usually lie between $_m$ and $2_m + 2$. The maximum variation in density due to the choice of a value for between these extreme limits is ± 5 p.ct; and as the amount of hydrocarbons in town gas is usually small, this approximate estimate of their density is sufficient. In a considerable number of analyses of town gas of C.V. 450 to 500 B.Th.U. gross per c.ft. which we have made by this method in Birmingham (1918-20), and Leeds (1924-5), the value of $_m$ keeps very close to an average value of 2·7. Assuming C_mH_n to be C_mH_{2m}, this leads to a mean density of 12·3 for the unsaturated hydrocarbons (air = 1·00).

APPENDIX II

Calculation of Air Injected and Products of Combustion Drawn in with Primary Air.

Assuming that the gas and air are both dry and the air free from CO_2,

Let a = vol. of CO_2 present in 1 vol. of dry gas.
b = ,, ,, ,, produced from combustion of 1 vol. of dry gas (including CO_2 already present—*i.e.*, a).
c = vol. of CO_2 present in 1 vol. of dry mixture of air and gas as determined by analysis.
d = vol. of CO_2 produced from combustion of 1 vol. of dry mixture over CuO. (including CO_2 already present—*i.e.*, c).
e = vol. of dry products of combustion from 1 vol. of dry gas (calculated from analysis and assuming all water condensed out).
f = vol. of water vapour produced by combustion of 1 vol. of dry gas.
x = vol. of dry air injected by 1 vol. of dry gas.
y = vol. of dry products of combustion drawn in per volume of dry gas.

Then $$a + y\frac{b}{e} = c\,(1 + x + y) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

And $$b + y\frac{b}{e} = d\,(1 + x + y) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Whence $$x = \frac{ade - ab + bc - bce + b^2 - bd}{bd - bc} \quad . \quad . \quad . \quad (3)$$

And $$y = \frac{e}{b}\left(\frac{bc - ad}{d - c}\right) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

If CO_2 is present in the air of the room (as distinct from that produced in the neighbourhood of the burner by combustion), then it can be shown that (3) can be expressed in the form :

$$x = \frac{ade - ab + bc - bce + b^2 - bd}{b\,(d - c) - eg\,(d - c)} \quad . \quad . \quad . \quad . \quad . \quad (3^A)$$

And $$y = \frac{ae - ce - (ce - eg)\,x}{ce - b}$$

where g is the CO_2 present in unit volume of air.

If the air of the room is free from CO_2, and there is no injection of products of combustion with the primary air, the above expressions reduce to the very simple form—

$$x = \frac{b}{d} - 1.$$

Prof. J. W. Cobb, in introducing the report, said: Mr. James Wood has been following-up the subject of the aeration of burners. At first the treatment was of a very general character; but that was followed-up last year by a more special study of some of the burners used in heating appliances—such as the gas fire and ring burner. This year the study has been carried further, and typical lighting burners have been subjected to careful examination. The results are presented in this report. You will notice that at the beginning of the report we have followed what is now our usual custom of placing first an introduction and a summary, in which a general account is given of the experiments and their results. The mass of information in detail which has accumulated in the progress of the work, and is necessary for its complete understanding and setting-out, is then placed later in the body of the report, where it can be followed-up by an interested reader. I may say that much experimental ingenuity has had to be expended to enable these results to be obtained, largely because the lighting burner is a much smaller and more delicate thing than (say) a ring burner. Possibly the most remarkable result from one point of view (perhaps I call it that because it surprised me and Mr. Wood also) was that the amount of primary air injected by an ordinary lighting burner, working normally with a good illumination, was only about half the total air requirement. The significance of this is that obtaining effective illumination from the burner must depend very much on how the rest of the air is supplied; and so it shows what importance must attach to the accessory fittings, which help to determine the way in which the secondary air is supplied.

One of the essential factors in the whole of this study of aeration has been the density of the gas. The determination by the effusimeter is apt to be erratic; while the making of a complete gas analysis is a very tedious process. But the gas engineer should have a means of determining density, and particularly changes in density, of the gas that he supplies. Mr. Wood has given both time and thought to this determination, and has examined in great detail the applicability of the method which, in essence, has been known for a long time, and a form of which was described by Mr. Blackie, of the Fuel Research Board. Mr. Wood finds himself able to describe that method, when applied with proper precautions, as being accurate and comparatively rapid in working.

Mr. James W. Wood then presented an abstract of the report, upon which there was no discussion.

Prof. Cobb: I quite appreciate the difficulty of framing criticism of a report of a highly technical character at short notice. But I should be very sorry if on this account we were deprived of any criticism, which members can send forward to me in writing.

The report was adopted.

FOURTEENTH REPORT OF THE RESEARCH SUB-COMMITTEE OF THE GAS INVESTIGATION COMMITTEE.

THE EXPERIMENTAL GAS PLANT AT LEEDS UNIVERSITY.

SIR CORBET WOODALL MEMORIAL.

Adopted by the Committee, May 21, 1925.

[For "General Introduction" see the Thirteenth Report.]

Introduction.

In September, 1917, Mr. Henry Woodall made the generous offer to erect and present to the University of Leeds an experimental carbonization plant in memory of his father, the late Sir Corbet Woodall. This offer was gratefully accepted by the Council of the University; but the conditions prevailing at that time prevented the carrying out of the project. When circumstances became more favourable, Mr. Henry Woodall commenced operations, and the plant was officially presented to the University at the opening ceremony held on March 26 last year.

The lay-out of the installation was designed by Mr. J. F. Scott after consultation with Professor Cobb and others. The original idea that the memorial should take the form of an experimental plant was due to Mr. W. T. Dunn, of the Institution of Gas Engineers. In the first instance, the suggestion was to erect one setting of retorts only, but the scheme grew until finally two settings, including both horizontal and vertical retorts, were installed. The cost greatly exceeded the first rough estimate; but so many friends of the late Sir Corbet Woodall expressed a desire to help, that it has been possible to erect the larger plant and to have a surplus in the form of an endowment for any future extensions and alterations. There are five companies with which Sir Corbet Woodall was specially connected, the Gas Light and Coke Company, the British Gas Light Company, the Tottenham District Light, Heat, and Power Company, the Bournemouth Gas and Water Company, and the Croydon Gas Company; and they have all been most generous in their help. Messrs. Humphreys & Glasgow offered a carburetted water gas plant, but it was decided that the make of gas for the smallest practical unit would be too great. Mr. A. G. Glasgow, however, insisted on giving a handsome donation. Messrs. Clayton, Son & Co., Ltd., of Leeds, who built the gasholders, scrubbers, purifiers, &c., made a substantial gift in money and supplied the apparatus on most advantageous terms. The Woodall-Duckham Company gave the setting of vertical retorts, Messrs. Gibbons Bros., Ltd., of Dudley, presented the horizontal setting, and Messrs. W. Parkinson & Co. were responsible for the gift of a meter. Messrs. Bryan Donkin installed the machinery in the exhauster house. All those concerned with the plant gave every possible assistance.

The first utilization of the plant has been made by the Gas Investigation Committee.

Dr. Parker and his assistants commenced operations last year, when the work at Birmingham had been completed. In the first place the many smaller fittings necessary in an installation required for investigations of the nature it was proposed should be conducted, were added; then gas making and carbonization trials on the horizontal retorts were carried out, and at the same time the performances of the condensing, scrubbing, purifying apparatus, &c., were examined. *The installation is not in any way a small scale model of a gas-works,* but has many features which differ greatly from usual practice. It was therefore necessary that preliminary trials should be carried out before a research programme designed towards the solution of definite problems could be commenced. The preliminary trials of the horizontal setting and of the condensing and purifying plant, &c., have been completed, and some alterations have been made. As a result of these tests and alterations, the suitability of the horizontal setting and auxiliary plant as a carbonization unit has been established, and tests of the vertical retort setting are now in progress.

THE EXPERIMENTAL GAS PLANT AT THE UNIVERSIY OF LEEDS.

Sir Corbet Woodall Memorial.

See Illustrations appended.

The Corbet Woodall experimental gas plant occupies a site, provided by the University, adjoining the Department of Fuel and Coal Gas Industries. The general arrangement of the plant is shown in plan in Fig. 1. The installation includes a setting of two horizontal retorts, a setting of two vertical retorts, and the usual condensing and purifying plant.

The setting of horizontal retorts is housed in the main building, and the vertical retorts are situated in an open yard. The gas from the horizontal retorts or the vertical retorts passes through the pipes A or B, provided with valves, to the air condenser, whence it travels through the exhauster to the scrubbers, the purifier, the meter, and the holders. Tar and liquor collecting pots are provided at the positions marked C, D, and E; and drain cocks are placed at the points marked F, G, and H. A gas-fired boiler is situated near the vertical retort setting; the boiler feed tank is adjacent to the air condenser, and a water meter is placed at position J. A photograph of the front of the plant is shown in Fig. 2, Plate 6. In the foreground is the horizontal retort house, and behind this are the vertical retorts, the exhauster house, &c. In the background the framework of one of the gasholders can be seen.

Horizontal Retorts.—The arrangement of the horizontal setting and the method of heating are shown in Fig. 3, Plate 1, which gives vertical and horizontal sections and elevations. The setting, which was designed and erected by Messrs. Gibbons Brothers, Ltd., of Dudley, contains two fireclay retorts of circular section. Each retort is 6 ft. in length and has an internal diameter of 12 in. From Fig. 3 it may be seen that the setting consists of two exactly similar halves with one common chimney for the waste gases.

Each retort is heated by six burners supplied with coal gas—usually town supply—and with air from a compressor situated in the exhauster house. The amounts of air and fuel gas for each burner are controlled by separate cocks, and the two gases enter a mixing chamber before travelling upwards to the burner nozzle. The amount of air which can be supplied under pressure is less than that required for complete combustion, if lighting back and overheating of the burner are to be prevented. An auxiliary supply of secondary air is therefore necessary. The burner tubes projecting vertically from the mixing chambers are narrower than the openings in the brickwork through which they pass, with the result that some auxiliary air is drawn upwards around the tubes. When maintaining the retorts at a temperature of about 1000° C., a further quantity of auxiliary air is supplied through holes of $1\frac{1}{4}$ in. diameter in the inspection doors marked C in Fig. 3. These openings are fitted with 1-in. nipples so that they can be closed when desired by means of caps.

Each burner is placed vertically below a silica brick supporting the retort, which is thus not submitted to the direct cutting action of the flame. The burning gases are deflected by the silica brick in such manner that they are divided into two streams travelling on opposite sides of the retort. The products of combustion then travel over the top of the retort and past three damper plates to enter a

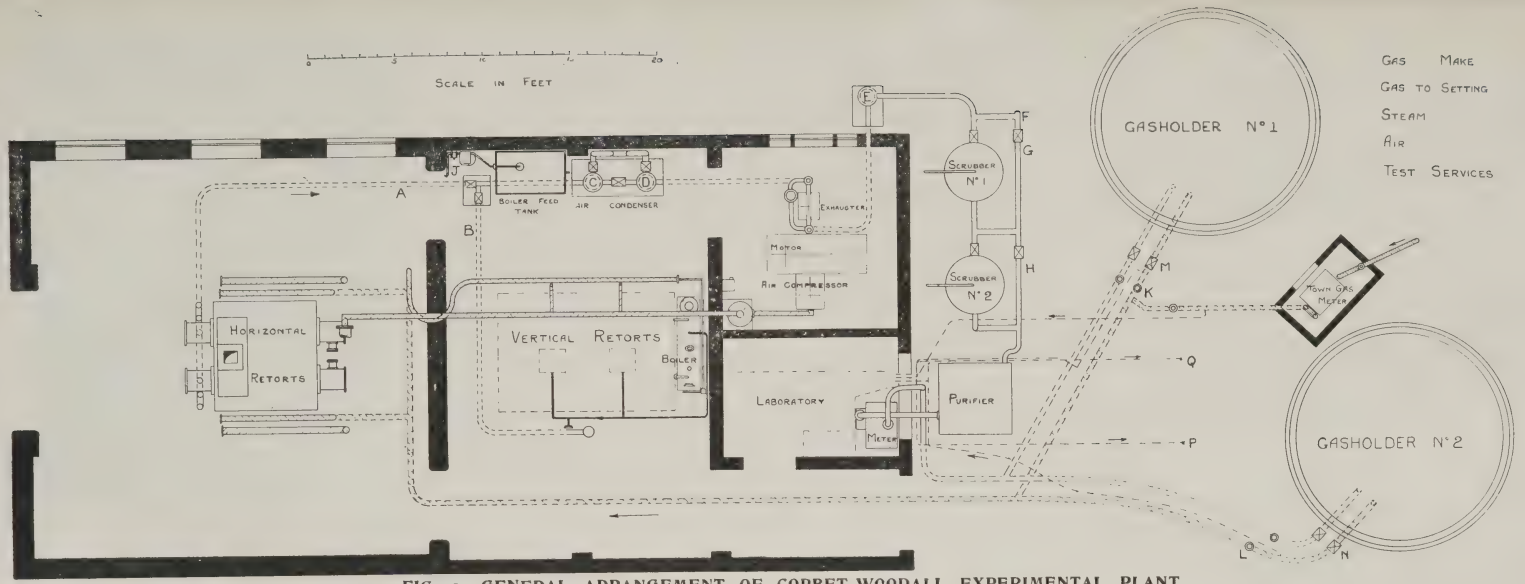

FIG. 1.—GENERAL ARRANGEMENT OF CORBET-WOODALL EXPERIMENTAL PLANT.

horizontal waste-gas flue on their way to the chimney, which is also provided with dampers. The air supplied to the burners is preheated by passage through a cast-iron pipe of 6 in. diameter, placed horizontally in the waste-gas flue above the retort.

It has already been mentioned that the retorts are 6 ft. in length. The end walls of the setting are 9 in. in thickness, so that the length of retort exposed to the heating gases is 4 ft. 6 in. Experience has shown that uniform heating of the retort can be secured over a total length of about 4 ft. This section of each retort, which can be kept at a uniform temperature, has a capacity of approximately 120 lbs. of coal with a heavy charge.

The mouthpiece of each retort projects 1 ft. 6 in. from the front of the setting, and is provided with a self-sealing door. The arrangement of the gas off-takes is shown in Fig. 4, Plate 2. According to this arrangement, the gas leaves the retorts by short descension pipes and then passes upwards through ascension pipes, each about 5 ft. in length, before again travelling downwards

Fig. 2.—Horizontal Retort House.

to the foul gas main underground. The lower end of each ascension pipe is fitted with an extension piece, 12 in. in length, which is sealed in a measured quantity of water. The retort valves are placed in the pipes leading from the upper ends of the ascension pipes to the main below ground level. The aim in this design is to remove all pitch by cooling the gas before it reaches the valves. This object has been fully achieved; for trials which have been carried out have proved that there is no deposition of solid matter either in the ascension pipes or any succeeding pipes. Pitch is deposited in a semi-plastic condition in the crosses immediately below the retort mouthpieces, but these deposits are readily removed when the retorts are opened for charging and discharging. Accumulation of pitch and consequent stoppage is thus avoided. The higher boiling fractions of tar condense out in the ascension pipes and flow down into the seal pots; and this steady downward flow ensures the ascension pipes being kept free from solid matter.

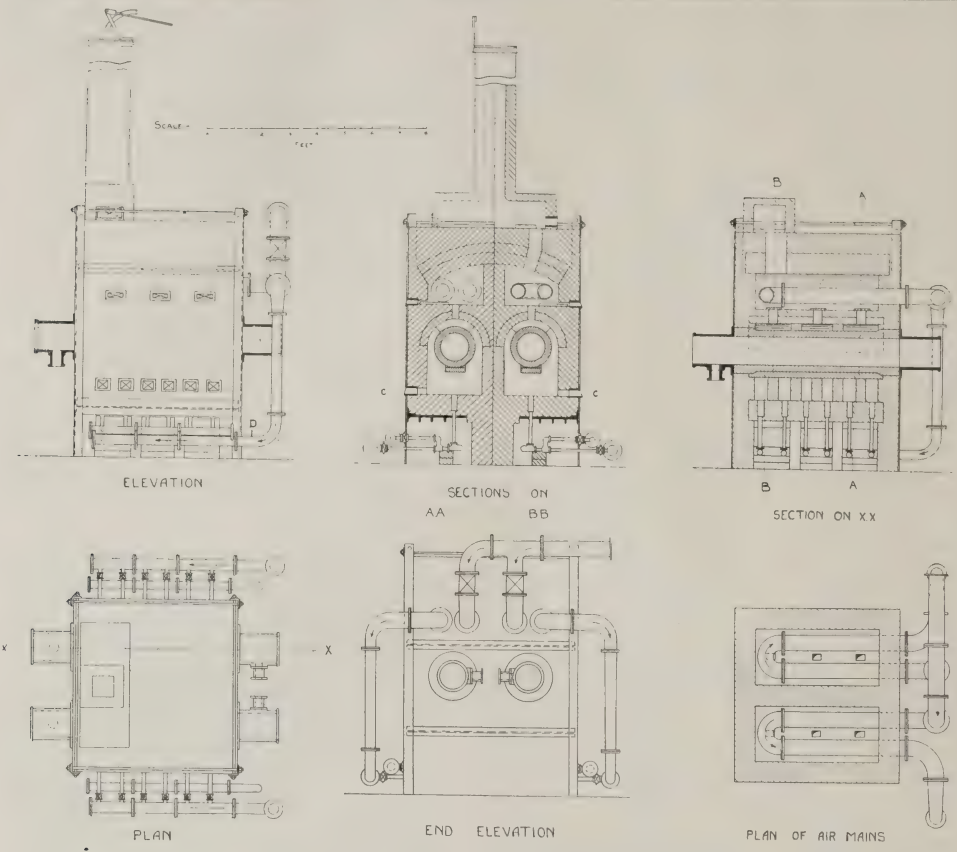

FIG. 3.—HORIZONTAL RETORT SETTING.

The fittings attached to the discharging ends of the retorts and the dispositions of the air supply pipes at this end of the setting are shown in the photograph, Fig. 5, Plate 6, and in several of the diagrams of Fig. 3. The metal castings bolted to the retorts are of the same dimensions as those at the front of the setting, and are fitted with self-sealing doors. Each casting is provided with a short length of 3 in. pipe on the side nearer the middle line of the setting. When normal carbonization tests are in progress, these pipes are closed by means of blank flanges, but if desired the blank flanges may be removed and the retorts connected by means of a short piece. This latter arrangement would prove useful in experiments in which it might be desirable to preheat gases or steam in one retort before passage through a charge undergoing treatment in the second retort; or it might be used for the production of water gas in one retort for passage through a charge in the second retort.

Vertical Retorts.—The vertical retort setting, which is situated in the open yard behind the horizontal retort house, was designed and erected by Messrs. Woodall Duckham, Ltd. The arrangement and method of heating are shown in Figs. 6 and 7, Plates 2 and 3, which give horizontal and vertical sections and elevations. Each retort, which is of silica material, is 8 ft. 7½ in. in length (excluding the coke chamber), and tapered from 8½ in. diameter at the top to 1 ft. 3 in. diameter at the bottom. The coal is fed into the retorts from the small hoppers at the top through close-

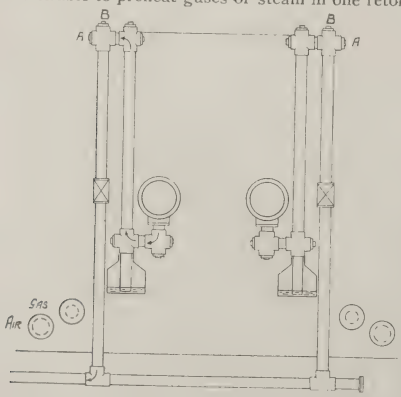

Fig. 4.—Horizontal Retort Setting—Gas Off-Takes.

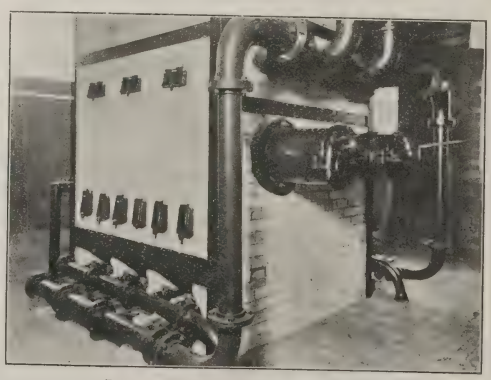

Fig. 5.—Horizontal Setting. Discharging End.

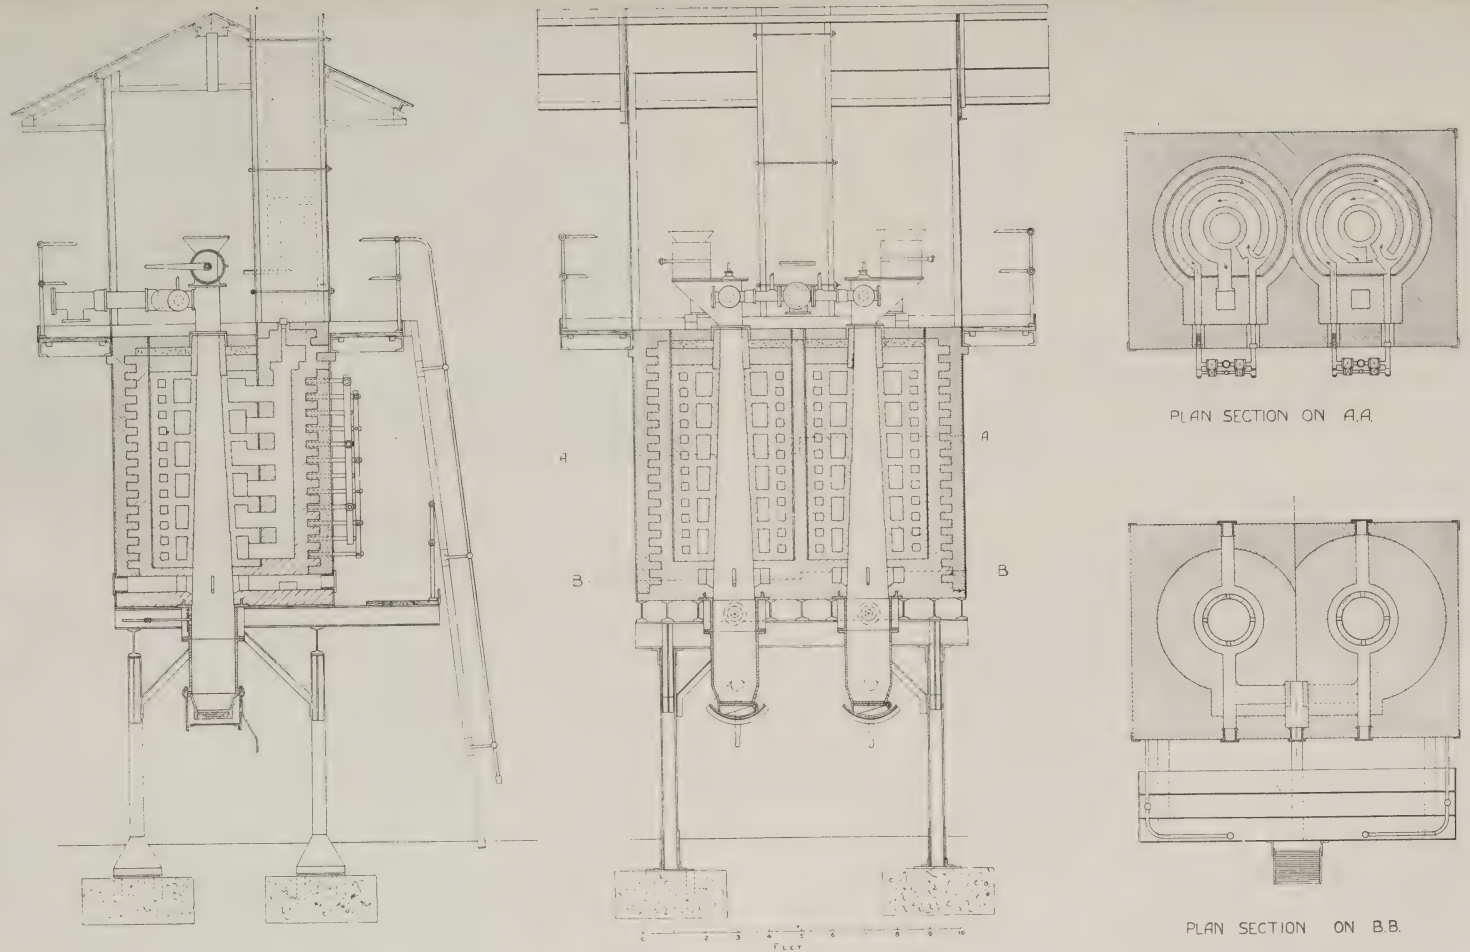

FIG. 6.—VERTICAL RETORT SETTING—SECTIONS.

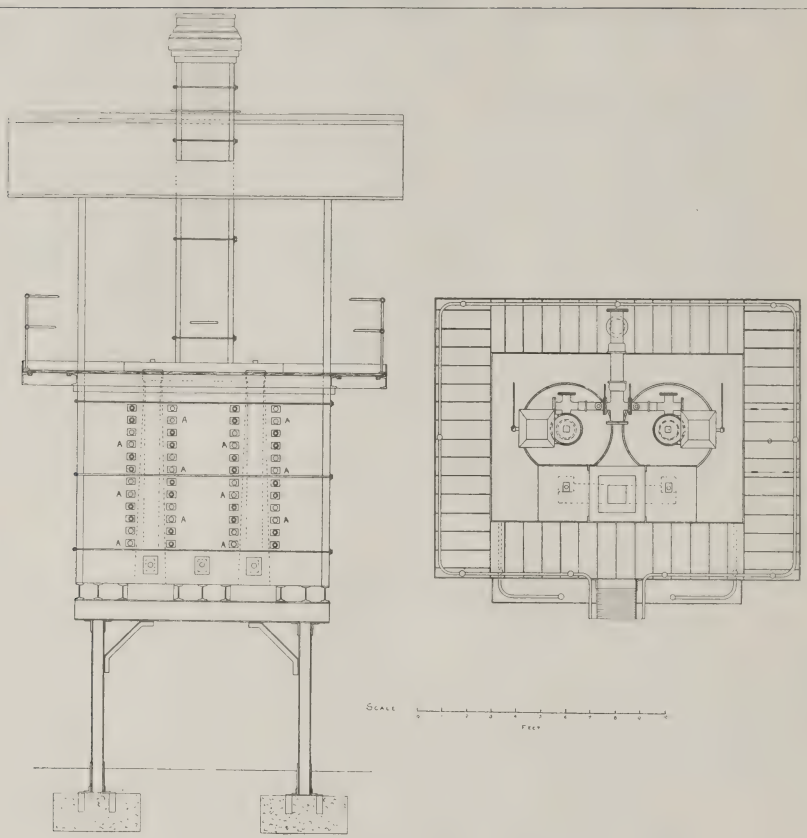

FIG. 7.—VERTICAL RETORT SETTING—ELEVATION AND PLAN.

fitting cylindrical valves. The coal is raised by chain and blocks to the charging platform, which is covered by a galvanized roof. The coke-cooling chambers at the lower ends of the retorts are 1 ft. 4 in. square section, and approximately 3 ft. 6 in. in length. No rotary extractor of the type usually found with continuous vertical retorts is provided; but the charge undergoing treatment rests on a hinged plate situated at the bottom of the cooling chamber. The coke chamber is water sealed in a movable quadrant provided with handle. When the quadrant is moved to one side, the hinged plate falls; and the retort may thus be discharged until the desired quantity of coke has been removed, when the coke chamber is again closed by the rapid movement of the quadrant to its original position.

The setting is heated by coal gas, usually town supply, and the air necessary for combustion is provided by the compressor situated in the exhauster house. The heating chambers for each retort are arranged in six circular horizontal tiers, each tier being under separate controls to enable the temperatures to be adjusted as required through the 6 ft. length of retort exposed to the combustion chambers. The capacity of the heated portion of each retort is approximately 2 cwt. of coal. The air and fuel gas supplied are preheated before mixing, by passage through separate flues surrounding each combustion chamber. The waste gases are collected in vertical flues communicating with a brick chimney which extends to a height of 16 ft. above the charging platform. The arrangement of the various flues is clearly shown in the diagrams of Fig. 6.

The lower end of each retort is provided with four openings which communicate with a common flue with damper adjustment. This enables the two retorts to be connected together at their lower ends, if desired. It is thus possible, as in the horizontal setting, to preheat gases or steam in one retort prior to passage through a charge undergoing treatment in the second retort, or to produce water gas in one retort for passage through a charge in the second retort. Means are provided for taking away the crude gas from either the upper or lower ends of both retorts. In both cases the crude gas passes downwards immediately after leaving the retorts, so that liquid products can be collected without having undergone further decomposition as a result of reflux action back into the retorts.

The air and fuel gas services at the front of the setting are shown in elevation in Fig. 8, Plate 3. A photograph of the front of the vertical retort unit is given in Fig. 9, Plate 6, which includes the charging platform, the burner-control stage, and the pipes supplying fuel gas and air to the setting. Fig. 10 is a view of the discharge end of the retorts.

Air Condenser.—The crude gas from the horizontal or vertical retort setting travels by the 3-in. main A or B (*vide* Fig. 1), situated below ground level, to the air condenser, which may be arranged in circuit or by-passed by suitable manipulation of the three valves provided. The construction of the air condenser and the dispositions of the valves are shown in Fig. 11, Plate 3; and a view of the upper portion may be seen on the left of the photograph, Fig. 9. The condenser is made up of lengths of 3-in. diameter pipe. The total length of air-cooled pipe is 46 ft., so that the cooling area is approximately 36 sq. ft. There are two tar and liquor collecting pots below ground level, the first at the inlet of the air condenser and the second at the outlet. Each pot has an internal diameter of 8 in., and its capacity to the bottom of the gas main is approximately 1·8 gallons. A drain cock is provided in the middle of the condenser, as shown in Fig. 11. When the plant is in operation this drain cock, which is left open, is fitted with an extension piece sealed in a vessel containing a measured quantity of water.

Exhauster and Air Compressor.—From the air condenser the cooled gas travels to an exhauster situated in a small room behind the vertical retort yard. The exhauster, which was supplied and installed by Messrs. Bryan Donkin & Co., Ltd., of Chesterfield, has a rated capacity of 800 c.ft.

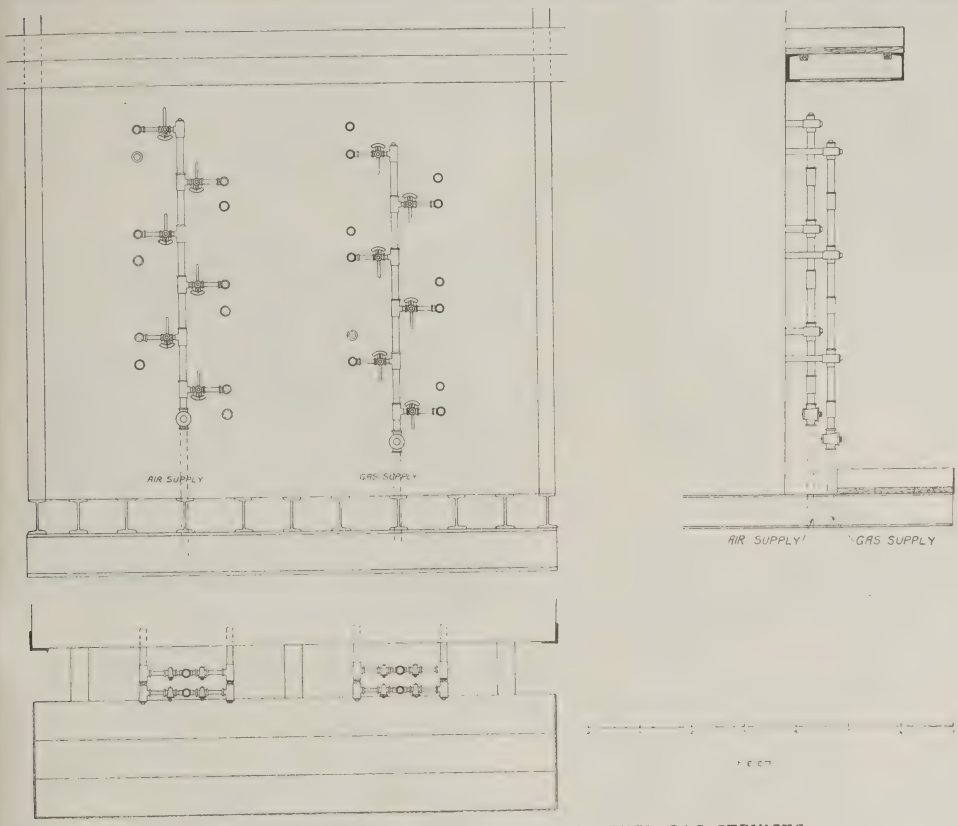

FIG. 8.—VERTICAL RETORT SETTING, AIR AND FUEL GAS SERVICES.

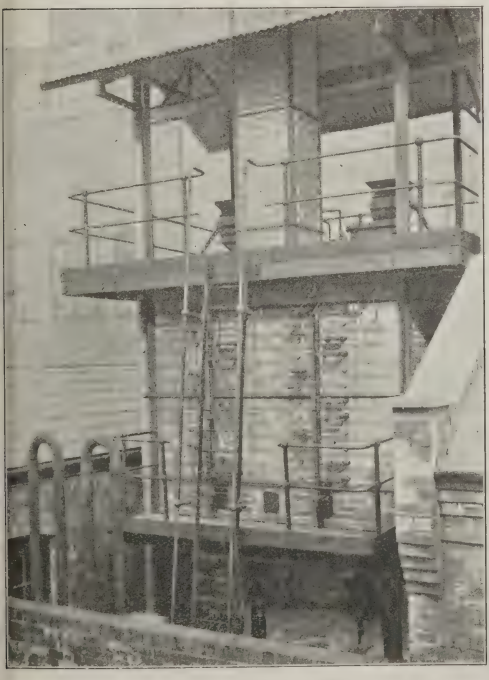

Fig. 9.—Vertical Retort Setting.

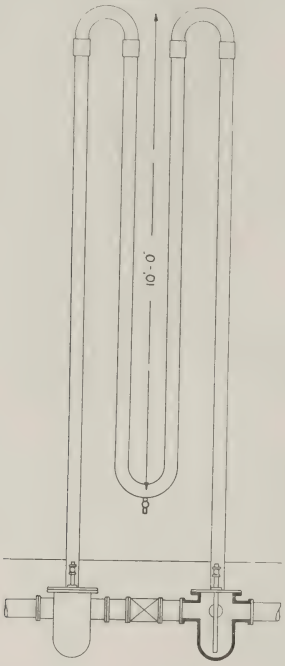
of gas per hour at 240 revs. per minute. It is belt-driven from a shaft operated by a 5-H.P. electric motor, the current for which is town supply through a switch with no-volt release. The motor, made by Messrs. Parkinson & Co., of Guiseley, Leeds, is designed to operate with 200 volt two-phase alternating current, 50 cycles per second, and with a shaft speed of 940 revs. per minute. The speeds of the motor and exhauster are not adjustable, but the

Fig. 10.—Vertical Setting, Coke Chambers.

pressure of gas at the inlet to the exhauster is controlled by means of a by-pass governor with balanced bell and conical valve.

The air required for heating the two retort settings is provided by a compressor which is also situated in the exhauster house, and was supplied and installed by Messrs. Bryan Donkin, Ltd. The compressor is belt-driven from



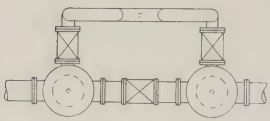


Fig. 11.—Air Condenser.

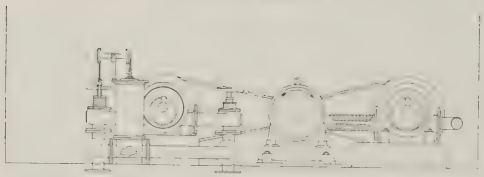

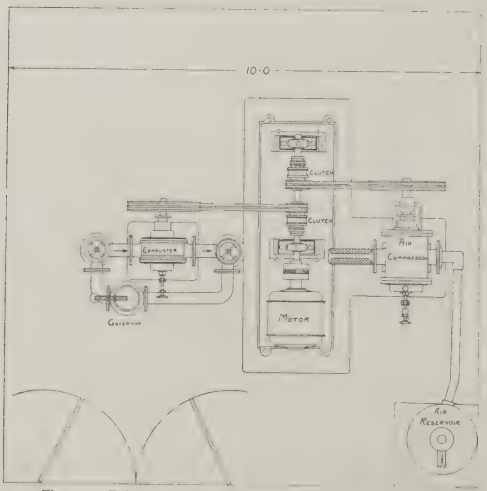

Fig. 12.—Exhaustor and Compressor—Plan and Elevation.

the motor shaft, and has a rated capacity of 4000 c.ft. per hour at a speed of 255 revs. per minute. From the compressor the air enters a reservoir placed in one corner of the exhauster house, and provided with weighted escape valve at the top and a mercury gauge to enable the pressure to be regulated to the required amount.

The exhauster and compressor are put in or out of gear by means of separate Hele-Shaw patent friction clutches.

The arrangement of the plant in the exhauster house is shown in plan and elevation in Fig. 12, Plate 3, and a photograph is given in Fig. 13, Plate 6.

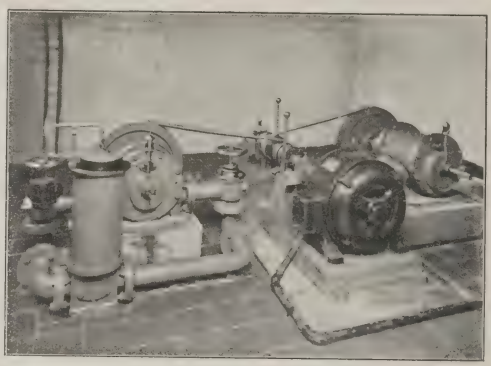

Fig. 13.—Exhauster and Air Compressor.

Scrubbers.—After leaving the exhauster, the gas is conveyed to two tower scrubbers erected by Messrs. Clayton, Son & Co., Ltd., of Leeds. A collecting pot is placed at position E, Fig. 1, in the service connecting the exhauster with the scrubbers. Both scrubbers are packed for a depth of about 5 ft. with porcelain rings supplied by Messrs. J. Macintyre & Co., of Burslem. Each ring is 1 in. external diameter and 1 in. depth, and the thickness of the porcelain is 1-10 in. The scrubbers, which are shown in elevation and section in Fig. 14, Plate 4, are 10 ft. high and 3 ft. internal diameter, and are fitted with water supply pipes and perforated plate water distributors at the top. The internal capacity of each scrubber, making due allowance for the volume occupied by the porcelain rings, is approximately 60 c.ft. The valves and connections are so arranged that either scrubber may be used alone, or the two in series, or both may be cut out of circuit.

Purifier.—The oxide purifier adjacent to the scrubbers (*vide* Fig. 14) consists of a box 4 ft. square and 4 ft. deep. The top cover is made gas-tight by means of rubber jointing material. The purifier contains three wooden grids, so that the purifying area is 48 sq.ft.; the internal volume, allowing for the space occupied by the oxide, is approximately 50 c.ft. A view of the scrubbers, purifier, and wall crane is given in the photograph, Fig. 15, Plate 6.

Meter.—The purified gas is measured in a 100-light wet meter supplied by Messrs. Parkinson & Cowan, Ltd. The meter, which is situated in the small laboratory adjoining the exhauster house (*vide* Fig. 1), contains a Warner and Cowan drum designed to compensate for any change in water level.

Holders.—From the meter the gas is led to one or other of two gasholders, occupying the positions shown in the plan, Fig. 1. Each holder consists of one column-guided lift of 1100 c.ft. capacity and a steel tank above ground level. The construction of the holders is shown by the diagrams in section and elevation in Fig. 16, Plate 4. Indicators are provided to enable the rise or fall of each holder to be conveniently measured at any time. The volume of the crown of each holder is 34 c.ft., and the capacity per inch rise is 9·25 c.ft. The pressure thrown by the bell is approximately 4·5 in. water gauge, and the volume above the water line when the bell is in its lowest position is about 120 c.ft.

Boiler and Steam Supply.—Provision is made for experiments on steaming, if these should be required. The steam is raised by means of a small Kirke gas-fired boiler, supplied by Messrs. Spencer Bonecourt, Ltd. This boiler, which appears in the photograph, Fig. 10, and is shown in section and elevation in Fig. 17, Plate 4, is designed to

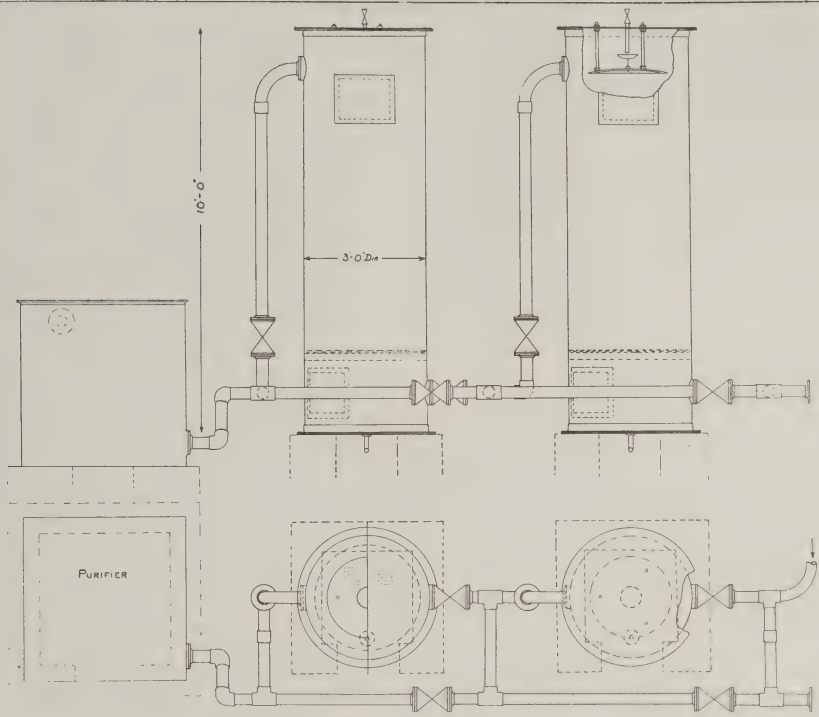

FIG. 14.—SCRUBBERS AND PURIFIER.

raise steam at a pressure of 120 lbs. per sq. inch. The water is fed into the boiler by means of a half-inch Simplex injector. From trials which have been made, it has been found that, with the maximum gas supply as at present arranged, the boiler raises approximately 50 lbs. of steam per hour at 100 lbs. pressure from water at ordinary temperature; the consumption of gas of a gross calorific value of 470 B.Th.U. per c.ft. is about 180 c.ft. per hour.

The services from the boiler are so arranged that steam may be admitted to the vertical retorts at either the upper

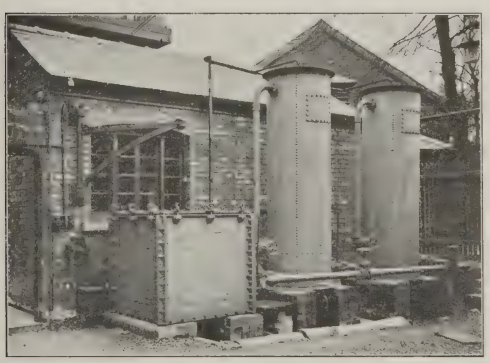

Fig. 15.—Scrubbers and Purifiers.

or the lower ends. In addition, steam may be supplied to the gasholder tanks through injectors which ensure the circulation of water. This apparatus has been installed to prevent the freezing of the water in the tanks during cold weather.

Measurements and Weighings.

Coal and Coke.—The coal supplied to the retorts is weighed in covered galvanized receptacles, on a portable platform machine supplied by Messrs. W. & T. Avery, Ltd. The beam of the machine is graduated in two scales to a maximum of 500 lbs. One division on the scale cor-

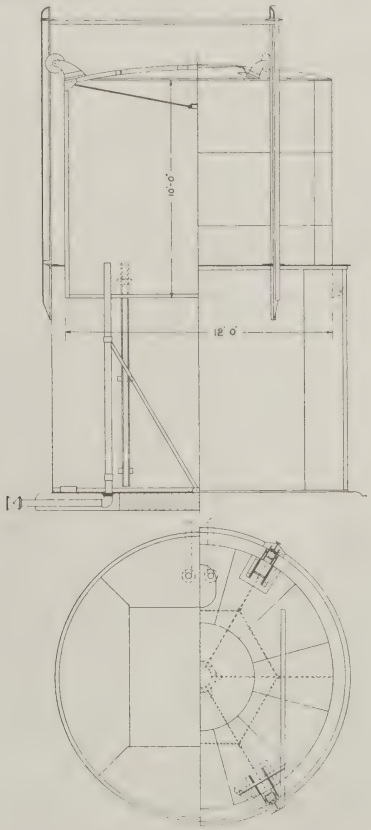

Fig. 16.—Gasholder.

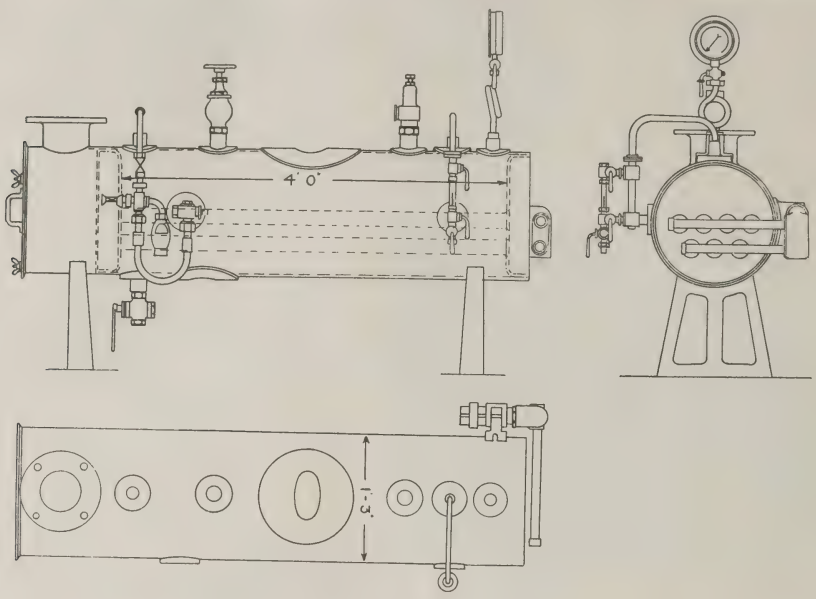

FIG. 17.—GAS FIRED BOILER.

responding with the main poise represents 25 lbs. and one division on the secondary scale represents 4 ozs. Each galvanized receptacle has a capacity of about 130 lbs. of coal, and since the machine responds to the nearest ¼-lb. the accuracy of the weighing is within 0·2 p.ct. The coke made is also weighed in similar receptacles on the same machine.

Tar and Liquor.—The amounts of tar and liquor, which separate out in the several pots situated between the retorts and the scrubbers, are transferred to covered galvanized tanks reserved for the purpose. Each tank, which has a total capacity of approximately 25 gallons, is provided with a drain cock at the bottom. After standing for some time, the tar and liquor are separated from one another and weighed in previously tared tanks. The amounts of tar and liquor are determined by weight, allowances being made for the known weights of water initially placed in the seal pot in the middle of the air condenser and in the pots in front of the horizontal retort setting. The volumes of tar and liquor are afterwards calculated from determined specific gravities.

Pitch.—In the case of the horizontal retort setting, the amounts of pitch removed from the crosses below the mouthpieces are collected and weighed at the end of the test.

Gas.—The make of purified gas is measured by the wet meter situated in the small laboratory adjoining the exhauster house. As a general practice readings, together with temperatures and pressures, are taken every hour; but on occasions readings are taken more frequently for the purpose of following the variations in the rates of gas evolution as carbonization proceeds. The meter is calibrated before and after each test. The make of purified gas as recorded by the meter is corrected for the amounts used for test purposes and taken at points prior to the meter.

Fuel to Heat Retorts.—The amount of fuel gas required to maintain the retorts at the desired temperatures is ascertained from periodic readings of the town-gas supply meter.

SAMPLING.

Coal and Coke.—The coal to be carbonized is sampled by placing a definite amount in a sample bin as each galvanized receptacle is filled for weighing. The amounts taken are then mixed, broken up into smaller pieces, and quartered down. The operations of crushing and quartering are continued until the sample has been reduced in amount to about 1 lb. The small sample is afterwards ground to a fine powder and used for the purpose of proximate and ultimate analyses and the determination of calorific values. The method of sampling the coke made is similar to that adopted for coal.

Tar and Liquor.—The tar and liquor, after separation from one another, are sampled from the 25-gallon tanks into which they are placed at the end of the test.

Pitch.—The quantities of pitch removed from the gas off-takes of the horizontal retorts are collected together, crushed, and quartered down. The operations of crushing and quartering are continued until the amount is reduced to about 1 lb.

Gas.—The outlet pipes of the two 1100 c.ft. holders are provided with plug cocks at positions K and L, Fig. 1, and with wheel valves at positions M and N. From a point between the plug cock K and the valve M of holder No. 1, a 1-in. gas service is taken and made to pass between the laboratory and the purifier, and thence to position P, where it is provided with a cock and a vertical pipe projecting about 4 ft. above ground level. A similar service from between L and N of holder No. 2 travels first behind the purifier and then to point Q. From both services branches are led into the laboratory. When holder No. 1 has been filled and the inlet and outlet valves have been closed, the holder is allowed to stand for several hours to enable the gas to become uniform in composition. The valve M and the cock P are then opened and gas is allowed to burn at the end of the vertical pipe at P. Meanwhile, calorific value and specific gravity determinations are made in the laboratory and samples are taken for purposes of analysis in an Orsat apparatus and in a Bone and Wheeler gas machine. The specific gravities are ordinarily determined in a Schilling's apparatus, and the calorific values in a Junker calorimeter as modified by the Birmingham Gas Department. The laboratory equipment also includes a Beasley recording calorimeter, which is used on occasions to record the calorific values of the gas leaving the holders. The method of examination of the gas from the second holder is similar to that described for the first holder.

The Beasley calorimeter is generally employed for the purpose of recording the calorific value of the gas made, as it travels from the purifier to the meter, a test service being run into the laboratory from the outlet of the purifier. Branches from this same service supply a Referee's sulphur apparatus, and provide the gas necessary for lead acetate paper tests.

The samples required for determinations of the amounts of sulphuretted hydrogen in the crude gas are taken from services connected to the gas main between the second scrubber and the purifier. These services are also used for long-period tests for naphthalene and ammonia.

Fuel to Heat Settings.—A branch service from the town gas meter to the laboratory enables tests to be made on the gas used to heat the retorts. Samples of the waste gases leaving the settings are drawn through silica tubes cemented into the brickwork at the bases of the chimneys.

Measurements of Temperatures and Pressures.

Horizontal Retorts.—The heating of the horizontal retorts is controlled by systematic measurements of the temperatures of the silica bricks situated above the burners. The silica bricks are sighted through the openings drilled in the inspection doors C, Fig. 3, and the temperatures are determined by means of a Cambridge optical pyrometer.

The temperatures of the charges at different points within the retorts are also taken on occasions. For this purpose four holes have been drilled and tapped in each of the self-sealing doors at the ends of the retorts. Iron tubes closed at one end are passed through these openings into the charges, and thermo-couples are placed in the tubes. The leads of the thermo-couples are insulated from one another by silica tubing. When the pyrometers are not in use, the holes in the retort doors are closed by metal plugs.

The temperatures of the air preheaters are measured by thermo-couples passed through the damper doors of the horizontal waste-gas flues. Pyrometers are also placed at positions D, Fig. 3, in the air mains between the preheaters and the burners.

The temperatures of the crude gas leaving the retorts are measured by thermo-couples placed in the top of the ascension pipes at points A of Fig. 4.

For the purpose of measuring the pressures at the top of the ascension pipes, connections are run from positions B (Fig. 4) to an inclined gauge so constructed that a movement of 1 in. represents $\frac{1}{10}$ in. water gauge.

Vertical Retorts.—The temperatures of the combustion chambers surrounding the vertical retorts may be determined by optical pyrometer sighted through the openings A of Fig. 7. These openings are ordinarily closed by conical brick plugs which can readily be removed. The temperatures of the products leaving the retorts may be measured by thermo-couples inserted in the gas off-takes.

Air Condensers, Scrubbers, &c.—The temperatures of the gas made are measured by mercury thermometers placed at the following points: (1) Inlet and outlet air condenser, (2) inlet and outlet exhauster, (3) inlet scrubber No. 1, (4) inlet scrubber No. 2, (5) inlet purifier, (6) inlet meter, and (7) outlet meter. The temperature of the air entering the compressor is also determined by a mercury thermometer.

Gas pressures are measured by means of a battery of vertical water gauges situated in the laboratory, to which connections are run from the following points: (1) inlet and outlet air condenser, (2) inlet scrubber No. 2, (3) inlet purifier, and (4) inlet meter. A vertical water gauge in the exhauster house registers the pressure at the outlet of the exhauster; and from a similar gauge outside the laboratory the pressure at the outlet of the meter may be measured. The pressure at the inlet exhauster is determined by an inclined gauge situated in the exhauster house, and the pressure at the outlet of the air compressor is registered by a mercury gauge.

Horizontal Setting, Preliminary Experiments.

		Oxygen	9·3
	100·0		100·0

Calorific value (gross) of dry coal, B.Th.U. per lb., 13,380.

When the retorts had been heated to about 500° C., they were filled with coke. The temperature of the setting was then slowly raised and every effort was made to obtain the maximum possible length of each retort at a uniform temperature. The maximum length which could be kept at a uniform temperature was about 4 ft., that is, within 1 ft. of the ends of the retorts. This maximum length was secured by heating the end combustion chambers to temperatures higher than those of the intermediate chambers, in order to allow for the losses of heat from the end walls of the setting. At temperatures of approximately 1100° C. the end combustion chambers were raised about 60° C. higher than the intermediate chambers.

When the desired temperature conditions of the retorts had been attained, the coke was discharged, and an iron stop was inserted in the discharge end of each retort. The iron stop consisted of a form of pusher with a circular plate of 10 in. diameter and a handle bent to rest on the end cast-

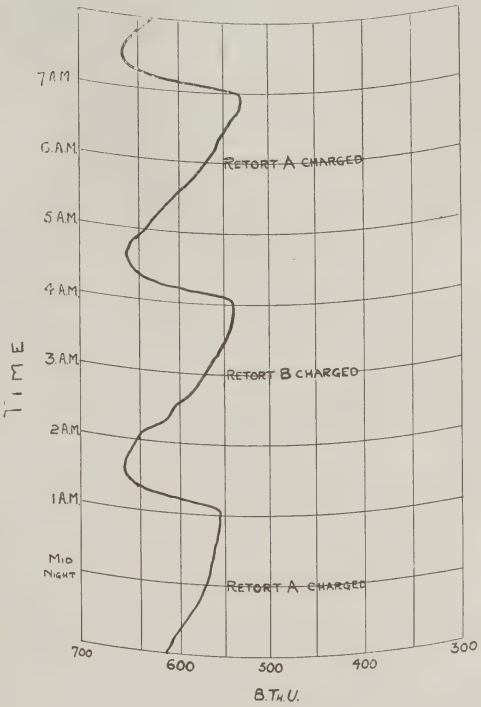

Fig. 18.—Calorimeter Chart.

ing of the retort. The stop was held in position when the discharging door was closed. The handle was about 2 ft. 3 in. in length, so that the stop occupied a position about 9 in. from the outside wall of the setting. The iron stop was removed each time the retort was discharged.

The coal, which had previously been broken to the desired size (maximum about 2 in.), was charged by hand until it occupied the portion of the retort at a uniform temperature. During this operation the charge was rammed several times, and the coal was prevented from dropping into the gas off-take pipe by means of a piece of sheet metal

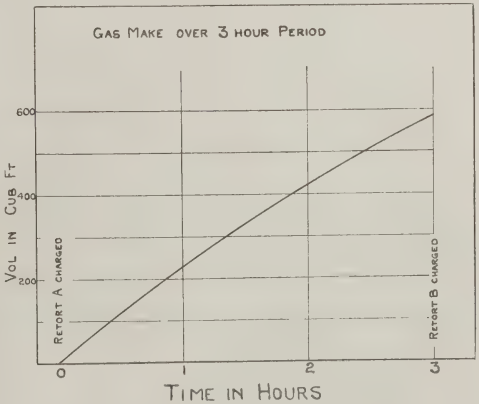

Fig. 19.

bent to fit the lower half of the retort mouthpiece. When the retort had been charged, the piece of sheet metal was removed and the door was closed.

The first trials were made with the object of determining the time required for carbonization with the combustion chambers at about 1150° C. Different charges were heated for periods varying from five to nine hours, and as a result it was concluded that the six-hour period produced a coke reasonably low in volatile matter. It was then decided to conduct trials in which the amounts of coal used and the products obtained were determined, and in which the proposed methods of operation could be tested.

Experimental Results.—The principal results obtained with the two horizontal retorts are given in Table II. Each retort was charged with approximately 124 lbs. of coal every six hours; and at the same time the pitch, which had collected in the off-take pipes below the mouthpiece, was removed. The operations of discharging, removal of pitch, and charging occupied from 10 to 15 minutes; the time occupied solely in charging was about 5 minutes. The two retorts, designated A and B, were charged alternately every three hours.

The amount of dry coke made was 13·3 cwt. per ton of coal, with a moisture content of 5 p.ct.; the coke contained 3·8 p.ct. volatile matter. The yield of gas of an average gross calorific of 603 B.Th.U. per c.ft. was 10,448 c.ft., which is equivalent to 63 therms per ton of coal. The amount of dry tar collected per ton of coal was 12 gallons, and the corresponding quantity of pitch removed from the gas off-takes was 16 lbs. The ammonia liquor recovered was equivalent to 23 lbs. of ammonium sulphate per ton of coal carbonized.

Since the horizontal setting contains only two retorts, the gas evolved varied greatly in quality during the progress of carbonization. The nature of the variations in calorific value is well brought out in Fig. 18, Plate 5, which is a copy of a typical portion of the chart taken from the recording calorimeter. This calorimeter was supplied with gas from a connection between the purifier and the meter. The variations shown by the chart are probably smaller than the actual variations in the quality of the gas as it passed through the foul main, owing to the mixing which must have occurred in the scrubbers and purifier. From Fig. 18 it may be seen that retort A was charged at about midnight; the door was closed at 12.14 a.m. As a result of the time required for the gas to reach the purifier and the lag of the calorimeter, the rich gas evolved from the charge did not commence to affect the chart until 1 a.m., when the recorded calorific value began to rise from a minimum of 555 B.Th.U. per c.ft. The calorific value then increased rapidly to a maximum of 670 B.Th.U. at 1.30 a.m., after which it fell more slowly to a minimum of 540 B.Th.U. at 4 a.m. At this point the rich gas first evolved from the new charge put into retort B at 3 a.m. had reached the calorimeter, with the result that the curve began to rise again.

TABLE II.—*Trial Test of Horizontal Retorts.*

Duration of test, hours	72
Coal carbonized, weight in lbs.	2,991
Coal carbonized per retort per day, lbs.	498
Duration of carbonization of each charge, hrs.	6
Weight of charge, average in lbs.	124

" " " " net per c.ft.	543
Thermal value of gas, therms gross per ton coal	63·0
" " " " net per ton coal	56·7
Specific gravity of gas (air = 1)	0·46
Gas made per retort per day (60° Fahr. 30 ins. saturated), c.ft.	2325
Tar (dry), gallons per ton of coal	12·0
Ammoniacal liquor, gallons of 10 oz. per ton of coal	27·3
Ammonium sulphate (pure) equivalent per ton, lbs.	23·0
Sulphuretted hydrogen, grains per 100 c.ft. at inlet purifier	600
Sulphuretted hydrogen, volume p.ct.	1·0
Ammonia, grains per 100 c.ft. at inlet purifier	0·3
Naphthalene, grains per 100 c.ft. at inlet purifier	0·7
Sulphur in purified gas, grains per 100 c.ft.	20·6

The rate at which gas was given off during a three-hour period from the charging of retort A to the charging of retort B is shown by the curve, Fig. 19. In this curve the total volume of gas evolved is plotted against time for a typical period of three hours. During the first hour the volume of gas was 230 c.ft., and at the end of the second hour the volume had increased to 425 c.ft., so that the amount for the second hour was 195 c.ft. During the third hour the volume collected was 160 c.ft. The curve thus illustrates the reduction in the rate of gas evolution as carbonization proceeded.

The average temperatures of the combustion chambers, as measured by means of a Cambridge optical pyrometer, are given in Table III. The combustion chambers for each

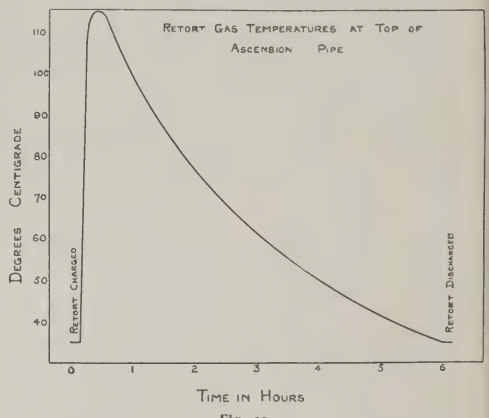

Fig. 20.

retort are numbered from the front or charging end to the discharging end of the setting. The temperatures of the end chambers, Nos. 1 and 6, averaged 1220° C., and the average of the middle chambers was 1150° C. The temperature of the air preheater in the horizontal waste-gas flues ranged between 700° and 800° C.

TABLE III.—*Temperatures of Retort Setting in Degrees Centigrade.*

6	1215	1226

The averages of the temperatures and pressures of the gas and air as measured at different points of the plant are given in Table IV. The retorts were operated as nearly as possible at level gauge. The temperatures recorded at the outlet of the air condenser and at all succeeding points

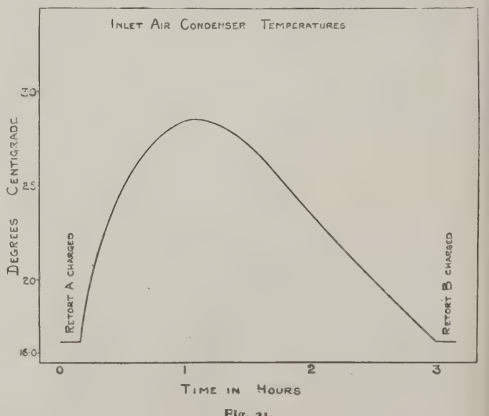

Fig. 21.

Fig. 22.

did not deviate greatly from the averages given in the table; and the variations which did occur were due mainly to changes in atmospheric conditions. The temperatures taken in the ascension pipes and at the inlet to the air condenser, however, varied as the carbonization of the charge in each retort progressed. Several series or readings, taken every five minutes during several hours, of the temperatures of the retort gases, as they travelled through the ascension pipes, were made. From these series, the curve given in Fig. 20 has been drawn by plotting temperatures in degrees Centigrade against time in hours. It may be seen from this curve that when the retort had been closed the temperature rose almost at once from 35° C. to a maximum of 115° C. The temperature then fell gradually until it again reached 35° C. at the end of the sixth hour, when the retort was due for discharging.

The temperatures of the gas at the inlet to the air condenser exhibited a three-hour cycle of changes, since the gases from both retorts passed this point of measurement and a charging operation took place every three hours. The nature of the temperature changes is shown in the curve, Fig. 21. When the first retort had been closed after being charged with coal, the temperature rose from 16·5° C. to a maximum of 28·5° C. at the end of one hour, after which there was a gradual diminution in temperature to a minimum of 16·5° C. when the second retort was opened for charging.

The temperature at the outlet of the air condenser averaged 6° C. (43° F.), so that the condenser is clearly of ample capacity.

APPENDIX.

The Preparation of Coke Sections.

The examination of a lump of coke with the object of determining its texture is normally a difficult matter, if it be desired to obtain an idea as to the size and shape of the pores, the wall thickness, and the general condition of the specimen. Micro-sections, as ordinarily examined by transmitted light, are usually much too small, and it is necessary to examine a number of sections to obtain information as to the structural differences existing in different parts of one piece of coke. For this reason, hand sections are also examined, but in these sections the shaded air pores do not show up well against the coke skeleton.

With these defects in mind, Dr. Rose, of the Koppers Company, has developed an ingenious method for revealing the structure of the coke, and for the details of the method we are indebted to Dr. E. W. Smith, of the Woodall-Duckham Companies. Essentially, the method consists in filling in the pores and cracks of a plane section with a suitable white cement and polishing the surface so obtained. The cement used is mainly plaster of paris with a proportion of admixed magnesia. The method has been tried by the Staff of the Research Committee for the preparation of sections of the coke made in the horizontal retorts of the experimental gas plant; and full-size photographs of two of the sections are reproduced in Figs. 22 and 23, Plate 6. From these photographs it may be seen that the cell walls of the coke are rendered easily visible against a strongly contrasting background, and that inert materials such as shale are clearly brought out.

Attention is drawn to this method of preparation of coke sections, since it is believed that it will prove valuable

Fig. 23.

in investigations in which comparison of the structure of coke made from different coals and by different methods is desirable. The preparation of micro-photographs of portions of the sections set in plaster of paris is at present in progress.

Prof. COBB, in introducing it, said: With reference to the Fourteenth Report, for convenience it is classified in that way as a report, but when you see it, you will notice that it is really rather a record interesting, we believe, to the Institution of Gas Engineers than an actual report upon the detail of scientific work. It consists essentially of a description of the experimental plant erected by the kindness of Mr. Henry Woodall, with some friends who wished to be associated with him, at the University of Leeds, as a memorial to his father, the late Sir Corbet Woodall; the description to serve as a record in the "Transactions" of the Institution of Gas Engineers of this valuable addition to the equipment of the Department of Coal Gas and Fuel Industries of the University. During the year Dr. Parker has been engaged in trying-out different portions of the plant, and making such adjustments in it as were necessary to fit it for use not only for demonstration purposes, but for the solution of the specific problems of the gas industry. As always happens in the case of a new plant of this sort—which of necessity departs in so many respects from standard practice in order to meet special needs—the time and labour required in getting it into operation have been considerable, in spite of the care bestowed upon it by its skilled and experienced designers. The Committee are greatly indebted to Dr. Parker for the work that he has been expending upon it, and hope to begin gathering the harvest in the near future.

Dr. A. PARKER said: In September, 1917, Mr. Henry Woodall made the generous offer to erect and present to the University of Leeds an experimental plant in memory of his father, the late Sir Corbet Woodall. This offer was gratefully accepted; but the conditions prevailing at that time prevented the carrying out of the project. When circumstances became more favourable, Mr. Henry Woodall commenced operations, and the plant was officially presented to the University at the opening ceremony held on March 26 last year.

The original idea that the memorial might take the form of an experimental plant was due to Mr. W. T. Dunn. In the first instance, the suggestion was to erect one setting of retorts; but so many friends of the late Sir Corbet Woodall expressed a desire to help, that the scheme grew until finally two settings, including both horizontal and vertical retorts, were installed. Mr. J. F. Scott, after consultation with Prof. Cobb, designed the general lay-out of the installation to meet the requirements of the site available and the units proposed.

The first utilization of the plant has been made by the Gas Investigation Committee. We commenced operations last year, when the work on the waste-heat boilers attached to the vertical retort settings at Windsor Street, Birmingham, had been completed. In the first place the many smaller fittings necessary in an installation intended not only for demonstration purposes, but also for the investigation of definite problems, were added. Gas making and carbonization trials on the horizontal retorts were then carried out; and at the same time the performance of the condensing, scrubbing, purifying apparatus, &c., was examined.

It must be emphasized that the installation is not in any way a small-scale model of a gas-works, but contains many features which differ from usual practice. It was therefore necessary that preliminary trials should be conducted before a definite research programme could be commenced. The preliminary trials of the horizontal setting and of the condensing and purifying apparatus, &c., have been completed; and certain alterations have been made. As a result of these tests and alterations, the suitability of the horizontal setting and auxiliary plant as a carbonization unit has been established. Tests of the vertical retort setting are now practically complete, and it is hoped we shall be able to embark on a definite research programme almost immediately.

The Fourteenth Report is a description of the experimental plant as it now stands; and, as Prof. Cobb has already stated, the description is given at this stage to serve as a record in the Transactions of the Institution of Gas Engineers.

As an appendix to the report a brief description is given of a method of preparation of coke sections as devised by Dr. Rose, of America, and brought to our notice by Dr. E. W. Smith. Attention is drawn to this method, since it is believed that it will prove useful in investigations in which comparison of the structure of coke made from different coals and by different methods is desirable. One section prepared as described has been brought along for inspection by those members who may be interested.

Mr. THOMAS GLOVER (Norwich): I do not wish to detain the meeting, but, as a member of the Investigation Committee who has taken an interest in this investigation from the earliest days, I am bound to say that I feel a little puzzled as to the definite research programme which we have in view at the present time. I hope that any members, outside the Investigation Committee, who have ideas will be kind enough to communicate them to us for our guidance and for our investigation.

Dr. Parker's précis of the report on the investigation of coke opens up, I think, rather a promising field. Coke at the present moment is a subject of very great importance to gas engineers, as at its best it forms such a large credit to the coal account. At the present moment we are face to face with considerable competition from the coke-oven people, who are grading their coke and entering into competition with gas coke, and are upsetting our market. I think we cannot do amiss by pursuing this investigation on coke, especially if it can be directed through practical channels which will help the industry to market its coke—after having produced the right type—and keep up the price as much as possible, and so keep up that credit to the coal account which has been so important in the past. I understand from an old student of the Institution who has been out doing important work in connection with vertical retorts in Boston and other places in the United States that this investigation on coke is an important matter at the Technical College in Boston, and that it is not always the best thing to place the coke in plaster of Paris. It is better to investigate the cavities in the coke by some addition to the microscope which helps to show-up the grain and structure and texture of the coke better than can be seen by the microscope alone or by the naked eye. All the same, we are interested in the specimens which Dr. Parker has exhibited. I had the curiosity to send Prof. Cobb some pieces from my works which I thought were better than those he showed me on the Investigation Committee. I do not know what is the position yet with regard to those samples, but I shall be glad to see them when they are ready for demonstration. Again, I would reiterate that the Committee would like ideas from the members of the Institution for the future work of this Investigation Committee.

Dr. R. LESSING: The last remark on coke by Mr. Glover encourages me to remind the members of the Institution that a similar method of dealing with coke samples was incorporated in a paper which I had the privilege of reading before the Institution thirteen years ago. An almost identical method for showing-up the structure of coke was then used; the only difference being that I employed then, and still do, wax of high melting-point to obtain the same effect. While specimens so prepared might not look so effective from a distance as the plaster of Paris ones do, they have the advantage that the wax can be easily removed by melting. Then we know the composition, and can study the coke under the microscope or by any other means, and analyze it as before. The specimens prepared in connection with my paper thirteen years ago were shown in some very fine photographs which are incorporated in the Transactions for that year. I should like to emphasize the point made by Mr. Glover that the study of the coke, and, obviously, of the processes by which the coke is made, and incidentally some gas, is of the greatest possible importance, and may actually mean a turning-point in our methods of carbonizing—at any rate in the methods of preparing the coal for carbonization. I have not the slightest doubt that these investigations will lead to results which will involve vital alterations in the processes to which we have hitherto been accustomed.

The PRESIDENT: I understand that there is shortly to be a meeting of the Investigation Committee; and I am certain that the Committee will be only too pleased to receive suggestions from any member of the Institution bearing on the work in view. I will ask Prof. Cobb to say a word.

Prof. COBB: I can only endorse all that Mr. Glover has said. The Committee are always willing to receive suggestions as to what lines of investigation are best calculated to develop the gas industry, and also on the subject of carbonization, which is the basis of the gas industry. I also endorse what Mr. Glover said about studying the structure of the coke. This is a suggestion which presents itself as being particularly suitable for our investigations, and it is one with which I entirely agree. As Mr. Glover knows, this is a subject which is coming up for discussion in more detail by the Investigation Committee tomorrow. Dr. Lessing's remarks confirm the importance of the subject, if any confirmation were needed. He also put forward, I will not say a claim, but something in the nature of a claim to have anticipated this method of preparation. Of course, Dr. Lessing knows perfectly well that not only with coke, but with other things, the impregnation of a porous substance with wax and other media for filling-up the pores is not a thing upon which one could take out a valid patent at the present day. It is simply that this method is very convenient, and it does give—as some of you may be interested in seeing, if you have not already seen it—a very vivid contrast, and makes a striking demonstration to the eye of the structure of a coke. I think you may be interested in seeing it, and I think this method, or this method modified as we may find necessary for the investigation of the finer pores, and so on, will prove exceedingly useful not only in our investigations, but in the investigations which may be undertaken by other members of the Institution. It was for this reason that, without being able to claim anything in the way of originality in connection with it—because it was brought to our notice by Dr. Smith—we thought it advisable to show one or two of these prepared specimens. I beg to move the adoption of the report.

The PRESIDENT: I have very great pleasure in seconding the motion.

The report was adopted.

NOTES ON THE TANKLESS GASHOLDER AT THE ETABLISSEMENTS ARBEL, DOUAI, FRANCE.

By L. ROLLAND d'ESTAPE, Ingénieur E.C.P.,
President of the Société Technique de l'Industrie du Gaz en France, and Hon. Member of the Institution of Gas Engineers.

The idea of eliminating from gasholder design the tank and the large volume of water contained therein, and substituting for them simply a vertical cylinder having a fixed base and an upper platform rising and falling in the cylinder, is not new. The difficulty of devising a gas-tight form of packing, either dry or wet, between the cylinder and the moving platform, had for long been the sole obstacle in the way of gasholder builders, until the problem was first solved in Germany, notably by the Maschinenfabrik Augsburg-Nürnberg, who have constructed a number of these tankless holders up to a capacity of 120,000 c.m. (nearly $4\frac{1}{4}$ million c.ft.).

The tankless gasholder at the Arbel Works at Douai, which is described in the present paper, was the first of its type built in France.* Work was commenced on it in 1922 by the Bonnet-Spazin Company, who are the licensees of the Augsburg-Nürnberg patent; and it was put into commission in 1923. The capacity of the holder is 27,500 c.m. (970,000 c.ft.), which could be increased on existing lines to 40,000 c.m. (1,412,600 c.ft.). Recently Messrs. Bonnet-Spazin have installed, for the Société du Gaz de Paris, three tankless holders of a capacity of 2000 and 3000 c.m. (70,630 and 105,945 c.ft.). They have also in course of construction the following holders: Sartrouville (15,000 c.m., 529,725 c.ft); St. Etienne Colliery Company (20,000 c.m., 706,300 c.ft.); and Bordeaux (30,000 c.m., 1,059,450 c.ft.).

The main features of the Arbel holder, which is illustrated in the plate appended, are as follows:

1.—An outer shell in the form of an upright 26-sided polygon anchored to a fixed base of 3 mm. ($\frac{1}{8}$ in.) plate on the ground. Two inlet and two outlet pipes M for the gas, all of them 500 mm. diameter (19·7 in.), are fixed to the base-plate.

2.—A movable roller-guided disc A, rising or falling under the pressure of the gas, like a piston, inside the shell.

3.—A roof over all.

The following are some leading dimensions of the structure:

Height from base-plate to eave of roof	36 m.	(118 ft.).
Diameter of circumscribed circle ...	34 m.	(111 ft.).
"Stroke" of disc	30·875 m.	(101 ft.).
Weight of disc	90 t.*	(88·5 tons).
Pressure thrown, W.G.	100 mm.	(3·9 in.).

(* t. = metric tons.)

The shell, the base-plate, and the roof form a rigid structure and offer the maximum resistance to the wind; while the moving disc functions under cover in an absolutely still atmosphere.

The most difficult problem is how to obtain gas-tightness between the periphery of the moving disc and the holder. The rubbing surface must not be dry, for then metal-on-metal friction would have to be contended with. The periphery of the disc is, therefore, fluid-sealed, and the liquid used is tar. Further, in order to ensure that the disc shall rise and fall smoothly, it is obvious that the inner surface of the 26-sided polygonal holder must be absolutely smooth; anything in the nature of a projecting rivet-head is, of course, out of the question. For this reason the holder has been developed in the shape of a polygon. As shown in the illustration, for each division of the holder there is a rigid mounting, shaped to fit the angle formed by adjacent sides of the structure. These angle-pieces join the base to the roof, act as guide-rails for the rollers B, and serve to connect the plates of the shell. These latter are 4 mm. ($\frac{5}{32}$ in.) in thickness, and are strengthened by outwardly flanging the edges, and fitting channel irons thereto. The plates thus strengthened retain a plane surface; while the method of construction enables all rivets to be exterior, thus preserving the smooth interior face of the shell.

There is nothing particularly noteworthy about the roof; it steadies the upper part of the holder, and constitutes with the latter and the base-plate a statically stable structure. In addition it prevents rain and snow from falling on and affecting the disc. A window O admits light into the interior of the holder, and a gallery Q and ladder P facilitate descent on to the top of the disc itself, whatever its height may be. The ladder is a double one, articulated, and conseqently absolutely secure.

The disc or piston A is built up of sheets, and is strengthened with trusses C. In its movement it is guided by as many pairs of radial rollers B as there are angles in the shell. Tangential guide-rollers are unnecessary, in view of the absence of wind-pressure effects. Round the periphery of the disc is the special gas-tight device which is composed of: (1) An annulus K full of tar (see enlarged view); (2) a series of counterbalanced levers which maintain pressure against fitted metal blocks immersed in the tar, and which adjust themselves automatically; and (3) a canvas bearing-piece, one edge of which is fixed to the disc and the other gripped between the blocks and the weighted levers. It will therefore be understood that there is no friction on the bearing-piece, which merely serves to support, over a width of a few centimetres, the weight of the column of tar.

Generally speaking, the depth of tar should substantially balance double the maximum pressure it is possible to obtain from the holder by heavily loading the piston. At the Arbel Works the pressure normally thrown by the piston is 100 mm.; but this can be raised to 300 mm. by loading the disc with concrete blocks weighing 180 t. (177 tons). The depth of tar in the annulus is therefore 626 mm. (25 in.).

The sealing ring does not actually touch the shell, and there is no contact of metal on metal, for there is always a gentle percolation of tar between them. The sliding of the seal blocks upon the shell can give rise to no wear and tear, since the sheeting and the blocks are continually being washed over by the tar; and the friction is absorbed not directly by the metal surfaces, but by the thin film of tar which they enclose. Thus, as the disc rises and falls, the annulus of tar acts as a brush, continually painting the internal surface of the holder.

A descent on to the disc gives immediate assurance of the perfect gas-tightness of the device. Not a bubble can be discovered on the surface of the tar, nor is there the slightest smell. Even without any tar at all the movable disc is sufficiently tight around its circumference to allow during the building of the holder of the gradual raising of the disc by air pressure from a blower; the disc being used as a working platform.

A very small quantity of tar is thus continuously percolating between the disc and the shell; and, flowing down the sides, is collected in an interior annular channel L surrounding the base-plate. Thence it passes through cast-iron pipes into external reservoirs. As the level rises or falls in the latter, floats respectively start or stop small electrically-driven pumps D which raise the tar through the pipe E to a further series of reservoirs F near the top of the holder, whence it flows down the walls to the tar well H of the disc itself. This well is divided at G into as many sectors as there are pumps—eight in the case of the Arbel holder. These divisions are necessary in order to maintain the proper depth of tar in the well, even in the event of the disc taking a tilt from the horizontal. For each division, however, a stand-by pump is provided to ensure the continued supply of tar in case of a breakdown. If too much tar is forced into one sector, the neighbouring ones are fed through overflows.

A $1\frac{1}{2}$ h.p. electric motor suffices to drive each pump; and the duration of run varies according to the viscosity of the tar—in summer not more than eight minutes per hour, in winter once in twelve or even twenty-four hours. The consumption of energy is thus infinitesimal.

The most satisfactory seal to employ is specially prepared tar. It is to be remembered that the same tar is

* Visited by members of the Société Technique du Gaz and the Institution of Gas Engineers on June 29, 1924, during the celebrations of the Jubilee of the Société and the centenary of the gas industry in France.

circulated over and over again. The essential qualities to ensure are constancy of composition and a certain degree of viscosity at low temperatures. Light oils that might volatilize must, therefore, be eliminated from it. The method of preparation is to maintain the mixture at 60° C. for three hours with aeration. On cooling to 15° or 20° below zero, it must remain sufficiently fluid for an ordinary glass rod (as used in the laboratory) to sink by its own weight, and even submerge itself sideways to some extent.

As a precautionary measure, if gas continues to enter the holder when the disc is at the top of its travel, safety outlets N are provided which are uncovered when the disc reaches its limiting position; and gas escapes into the open air—an arrangement involving no danger, inasmuch as the outlet is at the highest point of the structure.

Tankless gasholders present the following advantages over those of other types: The necessity for warming the tank and the cups is removed; and the possibility of accidents from ice during unexpectedly cold weather or through carelessness during a frosty spell is avoided. Further, there is the saving of the cost of installing the boiler and pipes, and of that of maintenance and running charges.

In telescopic holders, pressures varying from 100 to 300 mm. (3·9 to 11·7 in.) are thrown (the inconvenience of this need not be laboured), while in tankless holders the pressure is constant, for it depends only on the weight of the movable disc as modified by the upward pressure of the gas. If working proves the advisability of so doing, the holder pressure can be increased simply by placing concrete blocks on the disc, without in any way interfering with the working. It has already been pointed out that in the case of the holder at the Arbel Works, the pressure can easily be varied between 100 and 300 mm. (w.g.).

As regards rigidity and resistance to the wind, the stability of the tankless structure is greatly superior to that of the column-guided holder. The disc moves in a closed box and a still atmosphere unexposed to gusts of wind. Columns, on the other hand, can be neither completely rigid nor absolutely vertical, and the lifts of the telescopic holder are subject to violent wind stresses.

Paint, which is an indispensable factor in the upkeep of tanks and lifts, in the case of the tankless holder need only be applied to the exterior of the shell. In other types of holder the interior of the tank, the lifts, and cups can only be painted when the water has been run out; and the metal oxidizes more quickly through being alternately in water and air.

It is impossible to inspect the greater part of the telescopic holder; and during every repair to tank or lifts, anything which falls into and deranges a cup entails draining the tank. In the tankless system the exterior of the holder is always available for painting, while the interior is continually being treated with a coating of tar from the disc annulus. If it is desired to increase the capacity, it is done simply by adding height to the shell, without in any other way encroaching upon the holder. This, however, is a fairly delicate operation, for which it is necessary to take the holder out of commission. As mentioned early in the paper, the Arbel holder has a present capacity of 27,500 cm. (970,000 c.ft.), which could be increased to 40,000 cm. (1,412,600 c.ft.).

In building a "wet" holder, in order to attain the required solidity, it is necessary to carry out much excavation and lay heavy foundations over the whole required area of ground. Settlements are by no means rare under the mass of water; tanks are apt to lose their shape or to crack; and repairs are difficult and costly. In the case of tankless holders, however, strong foundations are only necessary beneath the foundation ring of the shell; and here an earth resistance of about 1 kg. per sq.cm. (15 lbs. per sq.in.) usually suffices. Inside the ring, thin concrete is sufficient; and in the case of the Arbel holder there is only a bed of clinker concrete 10 cm. (3·9 in.) thick beneath the base-plate. Under the foundation ring of the shell there is broken-brick concrete 3 m. (9·8 ft.) deep and 30 cm. (11·8 in.) thick on a base 1·60 m. (5·2 ft.) wide by 23 cm. (9 in.) high. The total pressure carried by the earth below the foundations, including an allowance for wind stresses, is 1·130 kg. per sq.cm. (16·5 lbs. per sq.in.); and if the weight of the foundations themselves is omitted, it amounts to only 0·692 kg. per sq.cm. (10·1 lbs. per sq.in.).

Against these advantages, the only inconvenience that can be set is possible irregularity in the working of the tar pumps, and their running costs. But it has already been explained that, owing to the arrangement of partitioning the wells and fitting them with weirs, several pumps can be out of action without the slightest danger arising; and, as for the consumption of energy, this is insignificant. The Etablissements Arbel are absolutely satisfied with the regular working of their holder.

As to financial considerations, it may be stated that, up to a capacity of 10,000 cm. (353,148 c.ft.), the cost of a tankless gasholder is substantially the same as that of a holder with tank. Above 10,000 cm. the tankless type of holder shows an economy in construction of 5 to 20 p.ct. in its favour, according to the dimensions. That there is not a greater saving is explained by the fact that, while the amount of metal needed is very considerably reduced, the necessarily precise plating work called for by the tankless design is costly.

Discussion.

The PRESIDENT: We have here a very interesting and valuable paper on the tankless gasholder. A number of the members saw the holder at Douai when we were in France, and were much interested. I was so much interested that I have been over to Paris to see one of the holders there at work and one under construction, and I venture to think that it will not be long before some of the municipalities and companies erect these holders in this country. There is no doubt that, though the ordinary telescopic gasholder with water, and a brick or steel tank, has served us well, there is a great deal to be said for the tankless design. One of the most important things is that, if we have tankless holders, we shall be able to supply dry gas, and that would be an important matter where gas is distributed over large areas. The tankless gasholder has passed beyond the stage of experimental work, and is now a practical reality. The author of the paper has told us that the tank at Douai is capable of being increased to a capacity of 1½ million c.ft. I believe in America an order has been placed for a tank of a capacity of 4½ million c.ft., and that on the Continent orders have been placed for very large ones. One of the largest and most prominent American gas engineers has informed me that, so far as his Company and those he represents are concerned, he should recommend in the future that they use tankless holders. I shall now be very glad to have comments upon the paper, and especially from those who have had practical experience in this construction of gasholders. At the same time I am sure I am expressing your opinion when I say that we feel very much indebted to the French Society for presenting us with this paper.

Mr. J. P. LEATHER: I think we must echo what the President has said in thanking our French friends for giving us this paper. With regard to the tankless gasholder, I need not go into the question of the advantages mentioned in the paper; but there occur to me one or two disadvantages. I will first name one which is not very substantial—that the holder is always up. A holder is always rather an eyesore, and we are sometimes found fault with for having huge ones projecting into the sky and obliterating the view. At any rate I have had that experience, because there has been rather strong condemnation of a holder I recently erected, on the ground that it prevents people having a view of the country. These tankless holders will always be up, and you will not be able to see between the piers. Another question that has occurred to me is that, after all, the wind must have a considerable effect on these structures. To begin with, the plates between the supports are flat, and a strong wind will certainly tend to bend them slightly inwards. Further than that, unless there is a fairly strong framing, the framing will yield just as much as the framing of an ordinary column gasholder. I know the question of the yield of the framing of the latter is treated differently in some Continental works from what we have been inclined to do in England. Certainly my own practice has been to make a fairly strong framing; but on some works on the Continent the framing does not seem to be made of anything like such large-section columns as we have here. With the tankless holder you have the pressure of the wind on the tank or on whatever you call the structure, just as much as you have in an ordinary holder; and when you have a strong wind, it must have some effect. And as the disc is naturally very rigid, there must be a tendency to alter the space between the disc and the tank at certain points. I do not know whether our friend who has read the paper can tell us anything as to the experience in this respect—whether anyone has been on the disc when there has been a strong wind, and seen what the effect is.

M. BARIL, who replied in French, said that in countries where the wind is very strong means are taken to make the holder more rigid by strengthening the flanges and sheets. The wind in some parts of the Continent is not so strong as in England, and it is not necessary to construct so rigidly as would be the case in this country. Where gales are usual, the diameter of the holder is increased.

Mr. R. J. MILBOURNE: I appreciate very much the paper

which has been read, giving a description of the gasholder which most of you saw when the Institution visited France last year. I have had the pleasure and the privilege of seeing not only that holder, but a number of others of the tankless type which have been at work for a considerable time; and on each occasion my mission was undoubtedly to find out the defects of this particular system, because, as no doubt you are aware, I am interested in a Company which has taken up the patent rights for Great Britain. I must say that we have never been able yet to find a gas engineer who is working these tankless gasholders to say that there is any disadvantage whatever; on the contrary, they all say that there is undoubtedly a great advantage by adopting this particular system. One of the principal considerations which, it appears to me, commends this design to the notice of the English gas engineer is that it prevents the corrosion of sheets, such as we have in an ordinary water gasholder. The exterior is very easily painted and very "get-at-able" from the platforms which, I think I might mention in answer to Mr. Leather, not only serve the purpose of giving easy access to the exterior of the holder, but are added in accordance with calculations to give the necessary strength to the whole of the structure. As to the point of wind pressure—undoubtedly there is a continual pressure on the surface of a tankless gasholder; but the type is in a much better shape and form to withstand the wind pressure than is an ordinary guide-framed or spiral holder. Another consideration which is well worth notice is the interior of the structure; from my experience, during the past few years at all events, due no doubt to the present methods of carbonization and probably purification, there is a greater tendency for the ordinary gasholder to corrode from the inside. Until 15 years ago it was my experience that the inside of a holder was as pure and as safe from corrosion as could be desired at any time, and that the action of the gas which was then made—I suppose you would call it "straight" gas—caused no inconvenience from any corrosion on the inside sheets. It has, however, recently been my experience that corrosion does take place from the inside; and I have had the opportunity of talking over this particular point with a very eminent gas engineer who visited England last year, who informed me that they found in the Colonies that this particular difficulty is causing them great concern. If that is so, the tankless gasholder undoubtedly offers a very excellent design for the prevention of internal corrosion, as the inside is continually coated with tar, and therefore corrosion cannot take place. The other little difficulty which might naturally at first sight appear, is the question of the working of the pumps; but as the writer of this paper has pointed out, there are a number of pumps, and at the time the holder is being erected the disc is practically tight without any seal of tar being added. At the time I first visited the holder at Douai, during erection, the disc was up—I should think within about 10 ft. of the top—but there was no apparent leakage, so that it does not seem to me from the experience I have had that the danger of leakage with these particular holders is very great. I do recognize, however, that the English gas engineer is particularly conservative, and will no doubt need to have an actual example in this country under test before this particular type of holder makes much headway. Of course in England this particular type of gasholder will have a very serious competitor, as regards the cost of the holder, in having to compete with the spiral holder; and I should think the economical size would be much above what the writer of this paper says is the case on the Continent. They do not on the Continent, for some reason which is best known to themselves, adopt the spiral holder; and it is only in England that we use that particular type of construction to any great extent. I do not know that I can add any further useful remarks; but Mr. Gill, who is present, has had the advantage of seeing the particular type which is being erected by the Americans, and no doubt he will be able to tell us something about them which will interest us.

Mr. G. M. GILL: I have really very little to say about the tankless gasholder, but there is one matter which might possibly interest you. When I was recently in America, the builder of the tankless gasholders there told me that he had orders for an aggregate capacity of 65 million c.ft., and included in that were two or three tanks of 15 million c.ft. capacity each. This, I think, shows you the way the American gas engineers at any rate are looking at this problem. Mr. Milbourne mentioned that this was the only country where the spiral holder has made any headway. In America there seemed to be hardly any—I think I did see a small one somewhere, but they have not taken up that design at all. I notice the old type of gasholder has been referred to as the "wet" holder. It may be that if the new type is the "dry" gasholder, that may be a reason why the American gas engineer has shown a tendency to adopt it. (Loud laughter.)

M. BARIL then gave the following supplementary remarks. The Société d'Eclairage, Chauffage, et Force Motrice, who supply the suburbs of Paris, also have a tankless holder of 6000 cub.m. capacity, which was successfully put into commission some weeks ago. This holder was ordered as the result of a visit by M. Bazille, Chief Engineer at the Gennevilliers Works, to holders of the same type in Mügeln (1000 cub.m.), Waldenbourg (27,000 cub.m.), and Staaken (60,000 cub.m.). The economy realized by us by installing this tankless holder is not great, but it was selected owing to the small space occupied—the diameter of a circumscribing circle is 19.5 m., while that of an ordinary one-lift holder of the same capacity would be 30 m. The "E.C.F.M." Company are very interested in these holders, and we wish to enlarge on the following features: (*a*) Means of access to the piston. In the improbable, but possible, event of a man being overcome by gas when inside the holder, the collapsible ladder, easy enough for an able-bodied man to negotiate, would present great difficulty to one burdened with an unconscious comrade; and to overcome this difficulty, manholes have in some instances been fitted to the shell at various points of the piston travel. (*b*) Tar for the joints. It is very difficult, if not impossible, to find a material exactly answering the specification of the builders. At Gennevilliers a mixture of dehydrated tar, 75 p.ct., and anthracene oil, 25 p.ct., is employed; but it will probably be necessary to increase the quantity of oil in the winter. (*c*) Pumps. In the event of a sudden drop in the temperature, it is probable that the pumps will labour in starting up, owing to the greater viscosity of the tar; they may even refuse to start, if driven by high-speed motors. The exposed piping, therefore, should be lagged. Further, as there is a danger of the electric circuit fusing, it may be advisable to start up the pumps by hand, and a safeguard is to run groups of pumps in parallel. Another danger lies in the possibility of the public electricity supply failing; and it is as well to have a private stand-by generating plant. As a final protection, a small tar tank sheltered from the cold may be placed under the roof of the holder.

Mr. FRANK PRENTICE (Ipswich): I should like to ask why such a large number of pumps are required to fill the tar receptacles. Is it not continuous all the way round, or are there a number of separate tar receptacles to be sealed, and therefore a large number of pumps required? It would be interesting to have a reply to this.

M. BARIL explained that several pumps are installed owing to the tar ring being partitioned. Otherwise there would be a risk of the tar flowing to one side and putting the structure out of level. He added, however, that, not being a constructor of these tanks, he was not able to discuss the small points of detail in design.

Mr. GEORGE C. PEARSON (Birmingham): I would like to ask if any troubles have arisen in connection with the canvas bearing-piece. It appears from an examination of the design that there is a canvas-bearing piece which holds the tar against the sides of the tank, and that the action of the piston rising and falling would rub it against the sides of the tank. If this canvas gave way, it might be a serious matter; and it might be very difficult to replace it.

Mr. JOHN FOSTER (Birmingham): Supposing you get a holder working up and down three and four times a day, as we do in Birmingham, what effect would that have on the top seal?

The PRESIDENT: In reply to the last speaker, when I was in Paris, the holder was rising and falling very intermittently, and was used very much more than an ordinary holder. I was told by the engineers there that they had no trouble whatever, and such working is, of course, a very much more severe test in the case of the tankless than in the case of the ordinary holder. I may say that there will be a model of the tankless holder at the Litchurch Works at Derby on Friday, and the members will be able to see it. I have arranged with Mr. Milbourne to be there, and he will be very pleased to answer any questions that may be put to him.

Mr. CHARLES F. BOTLEY (Hastings): I am sure we all appreciate the fact that our friend from France has addressed us in our own language in reading this paper—a task which some of us would not like to essay in the opposite direction. He has also given his replies in his own beautiful language, and we have had our friend M. Zollikofer to interpret them for us. I should like to have added a remark or two; but as we are going to view a model, perhaps my questions will be answered then. At the same time I must express my disappointment that this design of tankless holder cannot be produced more economically. It seems to me a great pity that something of this kind is not available at a lower cost. Also might I venture to say that there may be other reasons for the corrosion of gasholders than that due to the kind of gas which is now manufactured. I think there are several with which most of us are acquainted. We are greatly indebted to our friend, and I have great pleasure in moving that we give him a hearty vote of thanks not only for the information, but also for being so good as to address us in our own language.

Mr. SAMUEL TAGG (Preston): I regard this valuable paper as a graceful extension of the kindly facilities which the French engineers offered us last year. I am sure we are very grateful both for the paper and to M. Baril for his services in reading it to us in the absence of the author. I have much pleasure in seconding the vote of thanks.

The PRESIDENT: I am sure it requires no words of mine to emphasize the vote that has been proposed and seconded. We all have very pleasant recollections of our visit to France, and we are delighted that some of our French confrères are at the meeting to-day.

The vote of thanks was carried with acclamation; and M. Baril briefly expressed his appreciation of the manner in which the paper had been received.

SELECTION, DESIGN, AND CONSTRUCTION OF NEW CARBONIZING PLANT AT STRETFORD.

By W. M. CARR, of Stretford.

The question of the selection of carbonizing plant is a problem which has become increasingly difficult during the last few years, owing to the great fluctuation in the relative values of coal and residual products. It is a problem with many varying aspects depending upon the situation of the gas-works, local conditions, available coal supplies, and residual markets; and the plant which most satisfactorily meets the requirements of one undertaking may prove less successful in another differently situated.

From the economic standpoint, the most desirable carbonizing plant is the one best equipped to meet the variation in the commercial values of coal and residual products. First, consideration must be given to the special requirements of the particular undertaking; and in this respect the efficiencies of various types of carbonizing plant, having regard to local conditions, come under review.

The types of plant in general use may be summarized as follows :

1. Complete gasification plant, giving a high yield in gaseous therms, with no residuals except liquid products.
2. Vertical retort installations, giving a high yield in gaseous therms with steaming, reduced quantity of coke of low calorific value, and maximum liquid products.
3. Coke and chamber ovens, giving a medium yield in gaseous therms, special quality of coke, and maximum liquid products.
4. Horizontal retort installations, giving a high quality of gas, with medium yield in gaseous therms, domestic coke, and residuals.

The variations in the arrangements of the above types of plant are well known, and are much too numerous to come within the scope of a paper of this description. It is the author's intention first to deal generally with the special circumstances affecting the selection of carbonizing plant at the Stretford Works.

The works, on transfer to the Stretford and District Gas Board in September, 1923, occupied a site of approximately 7⅕ acres adjoining the Bridgwater Canal. The first work carried out by the Board was the laying down of a railway siding, which, owing to the situation of the main line and existing plant, had to be brought in on the side of the works opposite to the canal. The then existing carbonizing plant consisted of two benches of 8 beds, each bed set with 8 horizontal retorts, 22 in. by 16 in. by 20 ft. long, D-shaped, in three tiers, with 6-in. ascension pipes on both sides of the retort benches, operated by an electrically-driven charging and discharging machine supplied from continuous overhead coal hoppers supported from cross girders on stanchions erected independently of the brick-built retort house.

Coal stores were provided on both sides of the house; and for handling canal-borne coal, a trunk elevator, shovel-fed from the barges, and a steel plate conveyor were utilized to convey the coal to a breaker pit and elevator on the canal side. A corresponding breaker pit and elevator was in use on the discharging side of the retort house; and this was also fed from the canal by means of an electrically-driven coal telpher and grab running on a reinforced concrete telpher track across the gable end, and thence parallel to the retort house to the breaker pit. The elevator on the discharging side was also used for feeding rail-borne coal, which was carted into the works to the retort house. The removal of coke from the house was by means of telpher machine and track passing through the gable end to storage ground, with quenching tank immediately outside the house.

The maximum capacity of the coal-gas plant was then 2,250,000 c.ft. per diem. In addition there is a carburetted water gas plant of a capacity of 500,000 c.ft. per diem. The maximum capacity of the gas-making plant was, therefore, 2,750,000 c.ft. per diem. It should be here pointed out that the condensing, washing, and scrubbing plant was barely sufficient to deal with the then maximum make of coal gas.

During 1923 there was a large increase in the consumption of gas. The send-out for the year was 641,000,000 c.ft., as compared with 485,000,000 c.ft., the output in year 1921. The maximum daily send-out during the winter of 1923-24 was 2,609,000 c.ft. compared with a maximum of 2,138,000 c.ft. in the previous winter. The margin of spare gas-making plant available was, therefore, exceedingly small.

The district served by the undertaking includes the intense industrial area of Trafford Park, as well as a rapidly growing residential area; and it was considered that in the laying-down of new plant it would not be prudent to take as the figure of growth the usually accepted figure of 5 p.ct. per annum compound increase, but to provide for 7½ p.ct., which is equivalent to doubling the output in approximately ten years. It was obvious that extensions could not be carried out without involving a large expenditure for the alteration and removal of existing plant, as the works, in part, were far too congested. Moreover, the coke and coal handling arrangements were cumbersome and costly in operation.

The general trend of development in carbonizing plant in recent years has been in the direction of obtaining the highest possible yield in heat units in the form of gas rather than in the form of gas and residual products. It will be freely admitted, however, that it does not necessarily follow that the highest yield in gaseous heat units will mean the cheapest gas, especially at times when prices of residuals are high in relation to the price of coal; and as the Stretford undertaking is situated in close proximity to the Lancashire and Yorkshire coalfields, where plentiful supplies of cheap gas-making slacks are available, this consideration was one which primarily influenced the author in the selection of plant.

The main points affecting the selection may be summarized as follows :—

1. The works are conveniently situated, with low carriage rates by rail and canal, for the purchase of cheap gas-making slacks. As an indication of value in this respect, it may be stated that the average price of good-quality washed or dry slack of ½-in. size is, on the values of the past twelve months, approximately, 6s. to 7s. per ton less than the price of gas nuts from the same seams. It was considered essential, therefore, that the selected plant should be capable of successfully carbonizing fine slacks.
2. A good local demand for gas coke exists in the area; there being large buyers for industrial purposes, and also a large and extensive market gardening demand in the out-districts.
3. In view of the rapid growth of the undertaking, it was considered desirable that the gas to be supplied should be of high calorific value, in order to defer as long as possible capital expenditure in providing mains of increased capacity, also in the provision of additional gas storage.
4. It was considered essential that the capital cost should be kept as low as possible compatible with efficiency, as the undertaking had recently changed hands, in the process of which the standing capital charges had been increased by 140 p.ct.
5. The plant generally should be such as could be worked in a manner to reduce to a minimum laborious work.
6. The conditions of the Gas Regulation Act necessitate at the present time that the yield of gas should be of a continuous and even quality.

It may, to a certain extent, be claimed that the three principal systems at present in use for high-temperature carbonization—*i.e.*, vertical retorts, chamber ovens, or horizontal retorts—would meet these requirements.

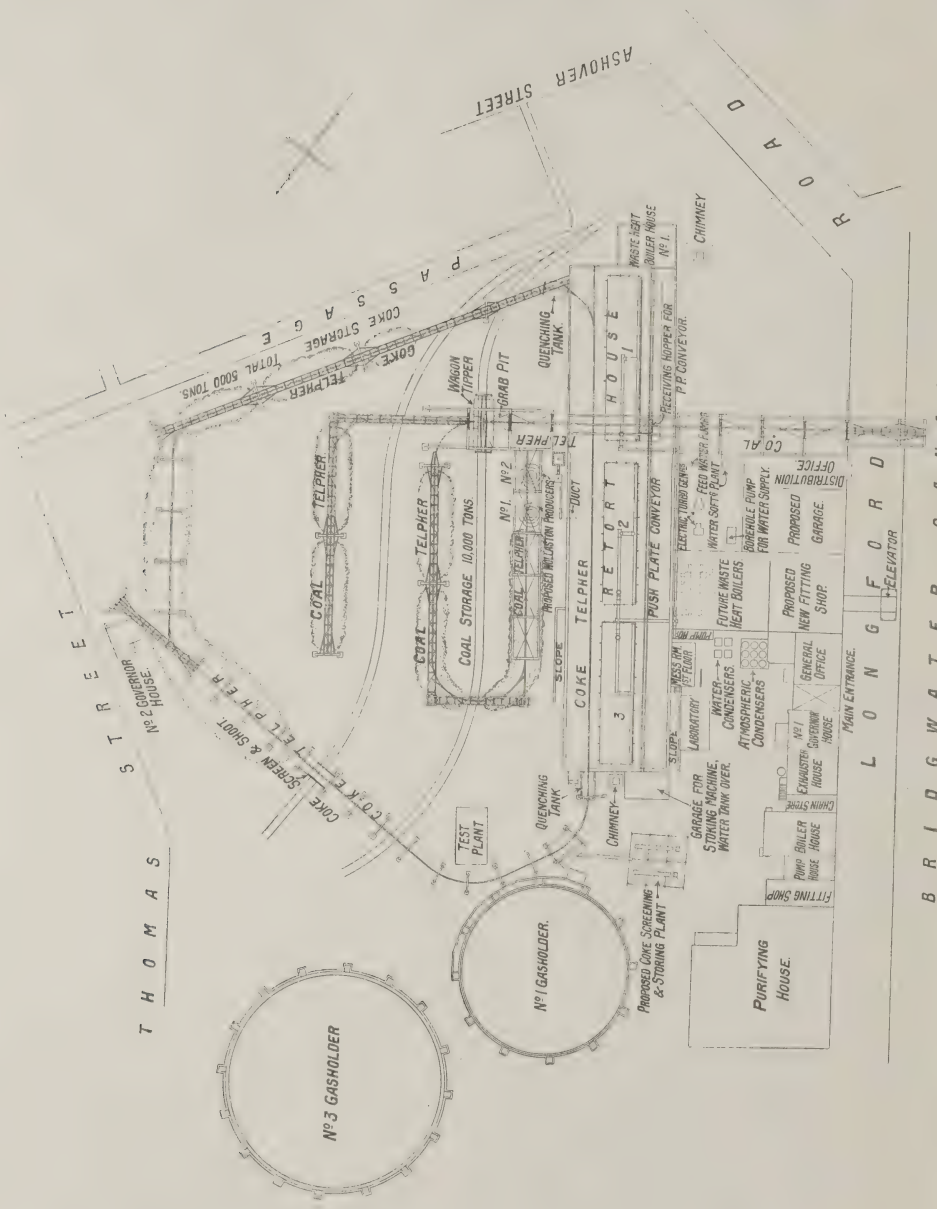

FIG. 1.—GENERAL SCHEME.

The advantages of a vertical retort installation over the other two systems lay in possible lower labour costs and cleaner working conditions. It was considered, however, that these would not outweigh the disadvantage in the matter of higher costs occasioned by restricted choice of coals, especially in the case of the Stretford undertaking, where only slacks are carbonized.

The small coke oven or chamber oven installation, such as has, in recent years, been extensively put down in America and on the Continent for gas-works purposes, offered attractions in that increased efficiency in the matter of fuel consumption was claimed in the case of ovens heated by means of reversible recuperators with gas from outside producers. The disadvantages of this type of plant are that the units are somewhat large for a medium-sized undertaking, and arrangements for charging and coke handling are not so simple as when dealing with smaller retort units. Moreover, with a large unit and long carbonizing period there is the possibility of greater variation in quality between charging times, especially having regard to the size of the plant as a whole.

Careful estimates were prepared of the probable working costs on a make of 650,000,000 c.ft. per annum, with a chamber oven and with a horizontal retort installation, taking the raw coke consumption of chamber settings with reversible regenerators and outside producers at 12 p.ct., and at 15 p.ct. in the case of the ordinary horizontal retorts, from which it appeared that the additional revenue from the extra yield of coke would be almost counterbalanced by the extra capital charges. Moreover, the class of coke produced from fine slacks in chamber ovens would probably have been unsuitable for domestic purposes.

There was a further consideration affecting the selection of plant—viz., that a portion of the new plant should be available for gas-making for the winter of 1924-25, in view of the increased output, and horizontal retorts, being more standard practice than chamber ovens, could be more rapidly installed. It was therefore decided to extend the existing horizontal retort house by the addition of a new bench of 9 beds, each containing 10 horizontal retorts 24 in. by 18 in. by 22 ft. long, and on completion of this extension to reconstruct the existing house, and replace the existing benches by two benches each of 8 settings on the same lines as the extension; making the total capacity of the extended and reconstructed carbonizing plant 6,000,000 c.ft. of straight coal gas per 24 hours, the whole of which could be operated by one set of stoking machinery, and coal and coke handling plant.

The advantages of the type of plant selected, so far as the Stretford undertaking is concerned, are :

1. Any class or grade of gas-making coal can be used down to the finest slacks.
2. The capital outlay necessary is the minimum, having regard to the site and conditions as to coal and coke handling.
3. Residual yield in the form of coke is high in relation to the coal carbonized, on account of more efficient heating and less radiation losses than with vertical retorts.
4. Maintenance charges are low, and horizontal retorts are easily repaired when in operation.

Fig. 2.—Wollaston Producer.

The carbonizing plant as laid down, and in course of construction, has several new and important features; and before dealing generally with the design of the plant, it would be as well to call attention to the circumstances which led up to the new departures in the arrangements for the heating of the settings. None will gainsay that considerable economies could be effected were it practicable to utilize coke breeze for the purpose of heating retort settings. At the time the type of plant to be installed was under consideration, the author had occasion to carry-out a series of tests on a gas producer installed for the purpose of boiler firing, which had been specially designed to gasify cheap slacks. In the course of these tests it was decided to test the producer running on coke breeze.

The plant in question was designed by Mr. T. Roland Wollaston, M.I.M.E., of Manchester, and consists of a producer of normal design with a super-imposed chamber or retort through which the fuel is passed over a series of trays, by means of mechanically-operated turning arms, until it reaches the producer itself (see fig. 2). The object of this retort is to enable the producer to handle a wide range of fuels, and to gasify fine slacks containing a large percentage of ash. Efforts have previously been made to coke or partially coke the incoming fuel to a producer by the outgoing producer gas, but with partial success only. The principal cause of failure was indirect heating causing uneven coking; and the swelling properties of the coal have prevented the free passage of the gas, and direct and intimate contact with the whole body of the fuel. In the "Wollaston" retort, the fuel is not packed together, but is spread out, and kept in motion in the chamber, in which there is ample room for the passage of the hot gas in intimate contact with the fuel. Further, the mechanical action ensures that all particles of the fuel are exposed and subjected to direct heat transference. As a result, a fair percentage of the volatiles are distilled off, and the finest slack on discharge from the retort is sufficiently coked to form a good producer fuel. When operating on coke breeze, the retort acts as an efficient drier; and no difficulty was experienced in successfully gasifying breeze which had been passed through a ½-in. mesh. It would appear, therefore, that the difficulties previously experienced in gasifying breeze in forced-draught producers were due to the moisture content closing the interstices in the breeze particles lying in close contact, so preventing the free passage of the blast.

As a result of the foregoing experience, the author concluded that there were considerable advantages to be gained by the use of outside producers which could successfully gasify coke breeze or the cheapest slack coals, as the fuel would be very much cheaper than the gas coke used in the self-contained producers. Against this, however, must be taken into account the radiation from the producer, and the sensible heat of the gas which is lost in the case of external producers. The difference in overall heat efficiency on account of these losses is approximately 16 p.ct.

Outside producers have previously been used for heating retort settings. The heating efficiency of such producers is, however, naturally less than the self-contained type using coke in both instances, but to the extent of utilizing coke breeze their economy is certain. An advantage of external producers is that a portion of the gas therefrom can, in case of necessity, be used as a diluent for the straight coal gas from the horizontal retorts, when it is desired to reduce the calorific value of the gas made to (say) 500 B.Th.U. for the purpose of distribution.

Following an investigation of the possible economies consequent upon the heating of the settings with gas from outside producers using cheap fuels, the question of heating by coal gas was taken into consideration, as it has often occurred, in the case of gas-works situated in the vicinity of the coalfields where cheap supplies are available, that the yield from residuals equals the cost of coal, or nearly so. In such instances, where there is a sufficiency of carbonizing plant, the heating of the settings by coal gas is an economic proposition.

Assuming the thermal efficiency of carbonization is 80 p.ct., and of gasification of coke in producers 75 to 80 p.ct., the cost per therm of coal gas or producer gas may be taken as being proportionate to the prime cost of the fuel; and, generally speaking, when the value of coke is higher than the price paid for coal, the heat units produced as straight coal gas are cheaper than the heat units produced from coke as producer gas.

The average efficiency of the ordinary self-contained producer utilized for heating retort settings does not normally exceed 80 p.ct. Allowing, however, for the advantage of the sensible heat of the self-contained producer gas, which is lost when firing with gas from outside sources, it is safe, for the purposes of making a comparison of the cost of gas and coke firing, to take 40,000 c.ft. of coal gas (of, say, 520 B.Th.U. per c.ft.) as being equal to one ton of coke.

Assuming the retort-house cost of coal gas 6d. per 1000 c.ft. (the actual net cost of coal gas averaging 520 B.Th.U. per c.ft. into holder at the Stretford Works during the twelve months ended March 31, 1924, was 5'7d. per 1000 c.ft.) the relative costs of heating by gas and coke are as follows :

Gas, 40,000 c.ft. at 6d. per 1000 c.ft. = 20s.
as against
Coke having a works value of . . . . 27s. 6d. per ton.

assuming that the coke consumed in the furnaces is $2\frac{1}{2}$ cwt. per ton of coal, would be :

Coke firing . . = 3s. $5\frac{1}{4}$d. per ton of coal carbonized
Gas firing . . . = 2s. 6d. ,, ,, ,, ,,

In the case of the figure of the cost of gas firing, there is, however, an additional $2\frac{1}{2}$ cwt. of coke per ton of coal which would be available for sale on the total throughout —equivalent to 3s. $5\frac{1}{4}$d. per ton of coal carbonized. After deducting the extra wages costs (at, say, 1s. 6d. per ton) on the additional weight of coal to be carbonized, the net cost of gaseous firing per ton of coal is $6\frac{3}{4}$d.—equivalent to a gross difference of 2s. $10\frac{1}{2}$d. per ton of coal carbonized. It should here be pointed out that no account has been taken in the foregoing figures for maintenance and capital charges on the extra carbonizing plant necessary in the above circumstances if the settings were entirely heated by coal gas; and a reasonable estimate for the above is 17d. per ton. This reduces the possible saving by coal-gas firing by one-half.

On the basis of the above figures, during the year 1924, had surplus carbonizing plant been available, and the whole plant adapted for firing by coal gas, a saving of approximately £4000 could have been effected on a make of 641 million c.ft.

The foregoing conclusions have been put forward in this paper as indicating the line of thought which led up to the evolution of the special regenerator setting which has been installed at Stretford.

It has been pointed out that it was essential that the plant should be in operation for the heavy load in the winter of 1924-25; and the time available would not permit of the immediate laying-down of auxiliary external producers such as the author has indicated, and which were then only passing from the experimental stage. It was decided, therefore, that the settings to be erected should be arranged with self-contained producers to work on normal lines, and, alternatively, for gaseous firing from external sources with producer gas, coal gas, or a mixture of both. It was considered essential to the efficiency of this latter provision that the gas and air for purposes of combustion should enter the combustion chamber of the setting at approximately equal temperatures; and to this end the author in conjunction with Mr. H. J. Toogood, of Messrs. Robert Dempster & Sons, Ltd., of Elland, the contractors for the retort benches, evolved a special setting which is provided with a self-contained producer of large area, and in addition has separate and distinct regenerator flues heated from the waste-gas flues, both of which are used for pre-heating the secondary air when the setting is working with its own producer, and which can be used alternatively for heating gas and air when firing with gas from external sources.

Design of Plant.

The general arrangement of the carbonizing plant, with coal and coke handling plants, is shown on the plan (fig. 1). A factor affecting the design of the coal handling plant was that the facilities for receiving coal by rail or canal should be maintained. At the same time, it was desired to concentrate the coal storage, as far as possible, on one side of the house, instead of on both sides, as existed. In order to provide sufficient space for the extension of 9 beds, it was necessary to remove a portion of the existing reinforced concrete coal telpher track passing across the gable end of the retort house. It was decided to adopt electrical telpherage for the coal handling, as by this arrangement the whole of the coal, except that required for stock, could be elevated in one operation. The new track between the Bridgwater Canal and the railway is carried over the top of the existing concrete trestles with girders spanning the retort-house extension, and is extended beyond the railway on steelwork towers and girders in two arms over the coal stores, running at right angles to the main track. The arm nearest the retort house is returned along the top of the old ferro-concrete structure parallel to the house to be utilized for feeding the proposed external producers.

The plant has a capacity of 40 tons per hour, and is capable of dealing with coal by means of a 30-cwt. grab either from barges on the canal or from the grab pit which is fed from the railway by a double-ended wagon tipper of the overhead type arranged to deal with 10-20 ton trucks, so that delivery from either end of the track is possible without turning round. To carry the super-imposed steelwork, and also the larger and heavier machine, the reinforced concrete structure is strengthened by means of external channels and internal angles strapped together across the columns of the concrete trestles, the

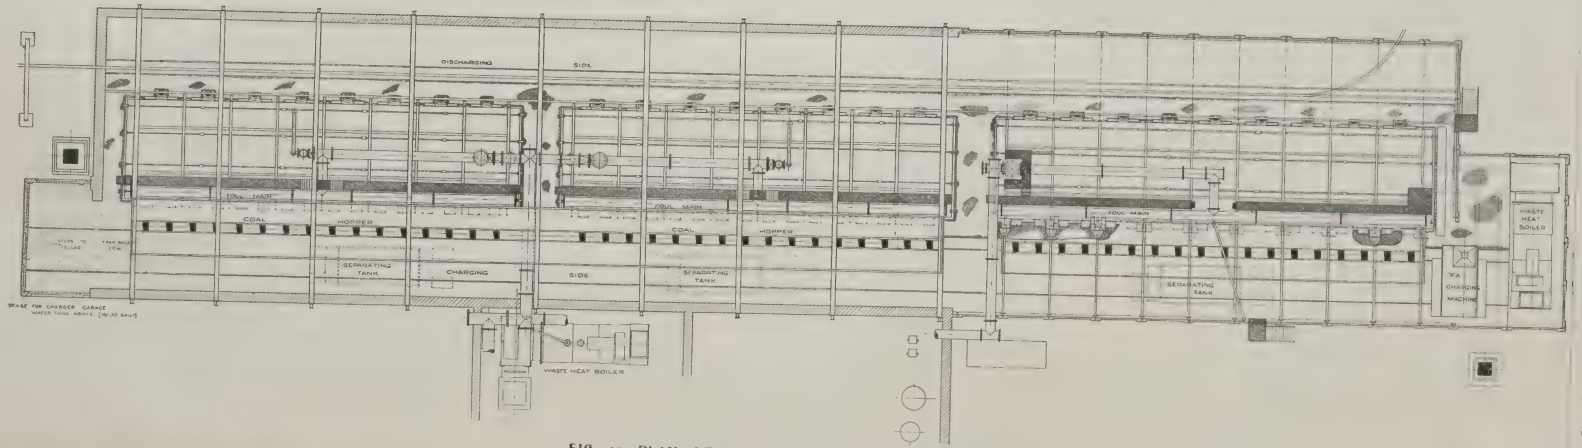

FIG. 12.—PLAN, NEW AND RECONSTRUCTED BENCHES.

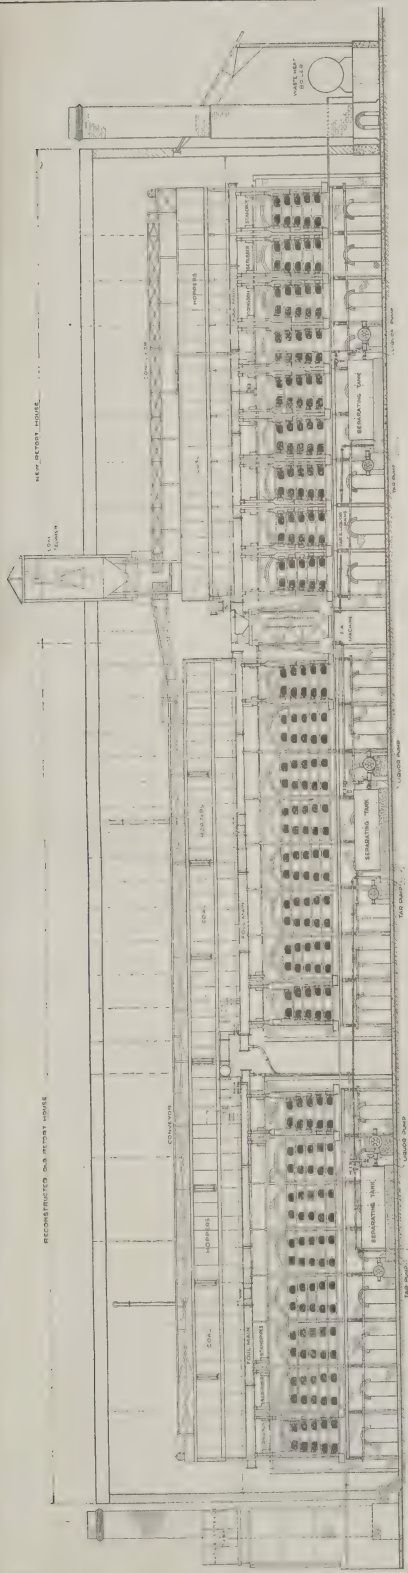

FIG. 13.—ELEVATION OF NEW AND RECONSTRUCTED BENCHES.

whole being braced with diagonal angles, the foundations being increased proportionately for the extra loading.

The increased height of the track over the existing reinforced concrete track is 23 ft. 6 in., making the total height 69 ft. It is carried over the retort house by 75 ft. span girders, and is roofed and sheeted with asbestos corrugated sheets to meet the retort-house roof. This cover forms the housing for the telpher machine. For weighing the coal received by canal barge, a Blake-Denison non-stop automatic weigher is installed on the telpher track between the canal and the retort house.

The general details of the coal telpherage plant are shown on the plans and illustrations appended (see figs. 1, 3, and 4*).

The coal is delivered by the telpher machine into a receiving hopper which, in turn, is arranged to feed the push-plate conveyors supplying the overhead bunkers in the extended house, and in the existing house, as shown in fig. 3. The coal hoppers and telpher track in the old retort house are carried on cross girders supported by steel stanchions independently of the building; and in order to provide for the larger benches with five tiers of retorts, these girders are raised by means of lengthening the existing stanchions 10 ft., and will carry the new coal hoppers and telpher track in the reconstructed portion (see fig. 7).

The overhead hoppers have a capacity of 48 hours, and are fitted with "A. & G." automatic doors which enable the stoking machine to take its charge as it travels from one retort to the next (see figs. 6, 7, and 8). The stoking

is done by a Fiddes-Aldridge simultaneous stoking machine, which is of an improved standard type in that the driving blocks for conveying the power from the charging wheel to the chain are on the inside of the chain instead of on the outside, as was the case in the original "F.A." standard machine (see figs. 9 and 10). The result of this alteration is that it is possible to increase the width between the side plates of the chain, and obtain greater capacity of coal, and, consequently, a much heavier charge than was possible with the old type of chain. This is further assisted by the special push plates, which are made of a light heat-resisting alloy. The charges are even; and on the withdrawal of the chain are left with a slight depression caused by the trigger of the front push plate in the centre of the charge, which ensures free passage of the gas and also reduces the distance which the heat has to travel to the core of the charge in the process of carbonization (see fig. 11).

The main reason for adopting the simultaneous machine as against the projector type is ability of the former to deal with the finest slacks and dant, without the creation of nuisance. Further, it has an advantage in quicker operation. The weight of charge can, with silica retorts, be burnt-off in an 8-hour period with combustion chamber temperatures of 1325° to 1350° C. The author considers that the latter temperature can only be exceeded at the expense of the life of the settings.

The general arrangement of the new retort benches in the extension and in the old retort house is shown on the plan and elevation appended (see figs. 12 and 13).

The retort settings (see figs. 14, 15, 16, and 17) are built in semi-circular arches 8 ft. 9 in. span with 18-in. pier walls between the neighbouring hot portions of the setting, and 14 in. pier walls below stage-level, between the relatively cold regenerators. The special double regenerator disposed on either side of the waste-gas flues is cellular in construction. The tubes are staggered so that all joints are covered, in order to prevent leakage. Further, a two-ply thin partition divides the descending waste-heat flues and the ascending secondary-air or gas flues, as the case may be. The construction is such that any crack which might develop in one tube is opposed by the wall of the adjacent tube. The depth from stage floor to cellar is 12 ft.; and the whole of this is utilized for the regeneration of waste heat. The waste-heat, secondary-air, and gas flues are controlled into each quarter length of the combustion chamber. The waste-gas tubes are horizontal, for easy inspection, and are sufficiently large to be repaired from the inside. The gas regenerator, which is on the outside of the waste-gas tubes, is similarly ar-

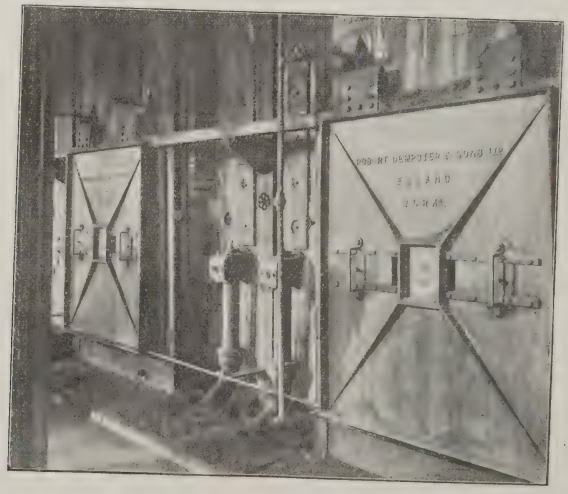

FIG. 18.—FURNACE DOORS.

ranged. The gaseous fuel or secondary air, as the case may be, is carried across the top of the waste-gas tubes, in cross ducts, to a large distribution chamber feeding the nostrils. The tubes in the secondary-air regenerator are arranged vertically, and the nostrils of both gas and air regenerators are brought into visibility in the combustion chamber.

The design of the producer is a good one; the furnace being 3 ft. 9 in. wide by 5 ft. 4 in. back to front with a fuel depth of 7 ft. In the author's opinion it is important, to procure the most economic working and even gasification, that the furnace should be as nearly square as possible. Much higher producer efficiency can be obtained with a wide furnace than with the long narrow shape which was the general practice for so many years.

The furnaces are fitted with non-clinkering adjustable screen-bar grates, and have a grate area of 26·25 sq. ft.,

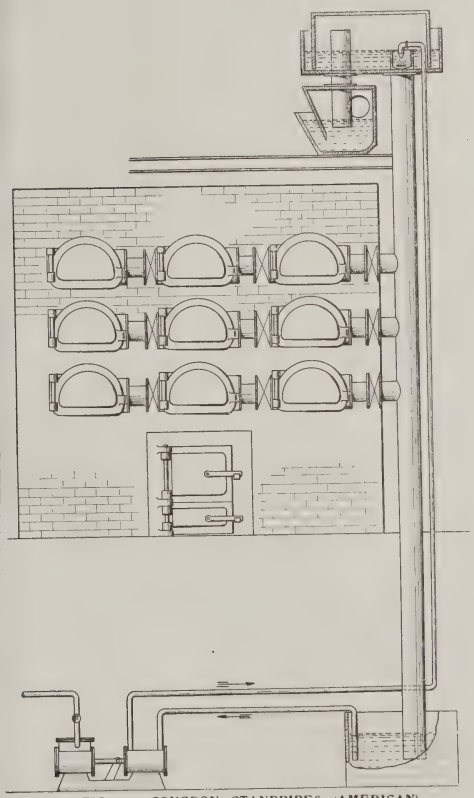

FIG. 19.—CONGDON STANDPIPES (AMERICAN).

2·39 sq. ft. per 20 ft. of retort. This form of grate obviates the necessity for clinkering, and facilitates an even rate of gasification; the whole grate area being maintained in a lively condition, as the air has ready access to the entire grate. Moreover, there is no dead fire resting upon the ash-pan itself. Provision is made for working the producers with steam or water; and at this point it may be mentioned that most satisfactory results have been obtained so far by the former method with almost dry ashpans. The charging doors are of the "Elland" double-sealed gas-tight type; the lids having an annulus which, with the door closed, forms, with the metal sealing face of the frame, a dust-retaining cavity completely surrounding the door, into which cavity dust and breeze swept from the retort-house floor is thrown. The sealing face is steeply inclined, so that the dust, on opening the door, falls away into the fire. The lids are hinged and operated on the Becton balanced lid principle, with counter-balance weights at the top of the bench (see figs. 16 and 17). The sliding ashpan doors of the producers are suspended from an overhead rail on a travelling bogey; and the door frames are flanged so that the machined faces of the frames and doors can be clamped to secure absolute tightness (see fig. 18).

The retorts, which are ⌂ section, 24 in. by 18 in. by 22 ft. long, are built up in 95 p.ct. silica segments, and are set in five tiers supported by thirteen all-silica stay walls 6 in. thick, with patent elliptical combustion-chamber arches in which the keystone is common to the producer arch and to the combustion-chamber arch. This prevents the lifting of the producer-gas arch by unbalanced expansion strains. The flues between the stay walls are 11¼ in. wide, so that, practically speaking, the very high proportion of 60 p.ct. of the retort is exposed for economic heat transmission—and this without sacrifice of strength. The stay walls are built with a saw-tooth edge construction where they abut on the pier walls, and between the retorts, to provide for after-expansion of the silica material (see fig. 14). The double provision for expansion at the point of highest temperature—*i.e.*, between the top three tiers of retorts—with the saw-tooth joints amounts to 2 in. It is interesting to note that, from observations on the heating-up of the settings, these joints have closed, as near as can be estimated, to ⅛-in.

For the purpose of firing the setting with coal gas, or producer gas from external producers, an 18-in. diameter gas main is carried beneath the cellar floor on both sides of the retort bench, and is connected to the auxiliary regenerators on each side by two 4-in. connections provided with a specially-designed gas valve for regulating the supply of gas to the setting (see figs. 16 and 18). The front walls of the settings and top of the retort bench are insulated with 4½-in. thickness of porous insulating bricks.

It will be observed from the foregoing description and a perusal of the diagrams that the setting meets all the requirements of modern practice as is generally accepted for efficient horizontal retorting with self-contained producers. With regard to the operation of gaseous firing with gas from external sources, it is proposed that the setting shou'd be first started-up under coke firing, and then changed on to gaseous firing either by coal gas or producer gas. It is desirable, of course, to close-off the producer; and the most simple manner of doing this is to charge the fire with a layer of breeze, which, after the closing of the primary air openings, will smoulder away, leaving the furnace fully ashed up. Alternatively sand or brickdust may be thrown on the surface. When passing back to coke firing, this can easily be broken-up. This procedure is only suggested as an additional precaution beyond the closing of the primary air openings, and the sealing of the furnace door. When the setting is being coke fired, the auxiliary regenerator is used for pre-heating the secondary air, which is admitted above the gas valve by means of a special port in the body of the valve above the seating. (See figs. 16 and 17.)

A departure has been made from standard practice in this country by the adoption of Congdon scrubber standpipes in place of ascension pipes and hydraulic mains. It has previously been mentioned that the existing condensing, washing, and scrubbing plant was sufficient only for the maximum make of gas in 1922; and it was considered that the adoption of the scrubber standpipe would assist in reducing the work on the purification plant.

The design of the standpipes as originally used in America (see fig. 19) was not, in the writer's opinion, such as would give efficient scrubbing or equal conditions as to pressure on all retorts; the pipe being of the same area throughout its length, though the volume of gas at the top is very much greater than at the bottom. The scrubbing effect on the gas from the top retorts must, in these circumstances, be very small.

A further objection to American practice was that the standpipes are reduced in area at the bottom, and connected to a tar pipe which conveys the tar and liquor to seal pots located in the cellar below the stage-floor, with possibility of stoppages arising in the down-take pipes, should any deposited pitch or carbon be forced through into the standpipes when cleaning the outlets from the mouthpieces. Moreover, the down-take pipes and seal pots prevent free access to the regenerator flues, and the seal pots themselves are not under the direct observation of the stokers on the stage-floor of the house.

After careful investigation, it appeared that the neces-

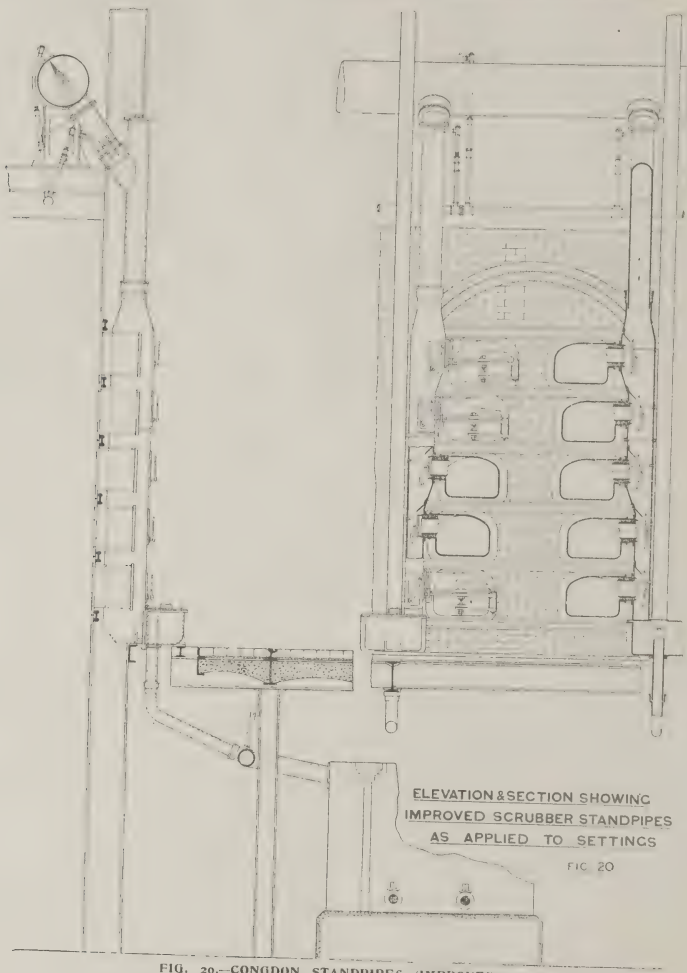

FIG. 20.—CONGDON STANDPIPES (IMPROVED).

sary conditions for the success of the scrubber standpipes were:

1. The area of the standpipe should increase in proportion to the volume of gas passing, to ensure maximum scrubbing effect and maintenance of equal pressure on all retorts.
2. The seal box to be at stage-floor level, the bottom of the standpipe forming a part of the seal box with direct access under the dip plate, should any foreign matter or pitch accumulate at the bottom of the standpipe.
3. Direct observation of the tar and liquor overflow from the seal boxes, which should be provided with tight covers easily removable.
4. The tar and liquor pipes connecting the separating tanks with the seal pots at stage-floor level should be arranged to avoid interference with access to the regenerator flues.
5. The standpipes to be suspended in such a manner as to allow free movement on the expansion of the setting taking place.
6. Connections between the mouthpieces and standpipes to be as short as possible, and allow movement, vertically and horizontally, to the extent of maximum expansion.
7. Provision to be made for quickly isolating any standpipe when required.
8. Operating valves for shutting-off retorts to be easily removable for inspection.
9. Connections between standpipes and foul mains to be of large area, and provided with expansion joints.
10. Liquor sprays to be arranged suitably, for easy cleaning and inspection.

An improved scrubber standpipe (see figs. 20, 21, and 22) was designed on the basis of these desiderata. The standpipe is increased in area by two steps; the maximum area being opposite the top retort. At this point it might be mentioned that, on the eighteen beds now under construction in the existing retort house, it is proposed to carry up the standpipe to a greater height above the top retort, with baffle plates to disperse the liquor and increase the scrubbing capacity (see fig. 23).

The seal boxes are made D shape; two standpipes being connected to each seal box, the bottom of the pipes being level with the bottom of the seal boxes. The dip plates at the front of the standpipes are arranged to give a seal of 6 in. The 4-in. overflow pipe is provided with a notched weir for measuring the rate of flow of the liquor from the standpipes. Easily removed covers are fitted to the seal pots, for inspection purposes, and for cleaning out when required.

The standpipes themselves are of cast iron in two castings. The bottom casting receives the connections from the three bottom tiers of retorts, and is formed to connect-up with the seal box. The top casting receives the connections from the top two tiers of retorts, and at the top is formed into a socket to receive the 9-in. diameter

connecting pipe to the foul main. The standpipes are 1 ft. 6 in. from back to front for the full height, $7\frac{1}{8}$ in. wide to the height of the second tier, $11\frac{1}{8}$ in. to the height of the fourth tier, and $15\frac{1}{8}$ in. wide at the fifth tier. The connections between the standpipes and the mouthpieces are 7-in. diameter, and are taken-off from the side of, and at right angles to, the mouthpiece; the distance between the inside of the mouthpiece and the face of the valve in the standpipe being $7\frac{3}{4}$ in. Socket pieces, which form a V-shaped valve seating on the inside, and $2\frac{3}{4}$-in. socket externally, are bolted to the standpipe; and the connection between this socket and the mouthpiece socket is made by a special sleeve, the external portion of which is ground to spherical radii struck from the axis of the sleeve at the centre of each socket, so as to permit free movement of the sleeve in any direction in its own packings when expansion is taking place (see fig. 20).

The valves, which consist of plain cast-iron spherical discs hinged to bell-crank levers, are designed for easy removal. The stuffing-box bearing mounting the axle to which the operating lever is connected is contained in a detachable plate bolted to the front of the standpipe; and the plate, with the valve attached, can be withdrawn by removing the set-screws securing the plate to the standpipe (see fig. 20). Inside the standpipes, immediately above each valve, deflection plates are provided set at an angle to the vertical side of the pipe, to deflect the liquor on to the face of the valve when open, to ensure: First, that the gas passing from the mouthpieces will meet a stream of liquor; and secondly, to assist in keeping the faces of the valves clean. A further object of these deflection plates is to prevent liquor travelling round the face of the valves, and so into the mouthpieces.

The standpipes are suspended from brackets attached to the front buckstays by hanging bolts, so as to permit of forward movement, on expansion taking place, independently of buckstays (see fig. 21). The 9-in. pipe connection to the foul main is carried vertically for a height of 4 ft. above the stand pipes, where a branch is taken-off at an angle of 36°, connecting into the bottom of the foul main. On this branch pipe there is a socket with special provision for expansion. There is also a faced joint immediately above the socket, in which an isolating disc can be simply inserted by the slackening of two bolts. A 24-in. foul main, to the bottom of which the standpipes are directly connected, runs the full length of the bench; the drainage of this main being through the standpipes themselves. The off-take from this main is at the centre of each bench, to ensure equal conditions as to pressure on all standpipes. Each bench of retorts is controlled by a 14-in. Cowan retort-house governor, and, in addition, Peebles' safety relief governors are fixed on each foul main at the centre of the bench, to provide relief in case of accidental stoppage of the exhausters. Liquor sprays are provided, one on each standpipe (see fig. 24), with two additional ones in the foul main itself. These sprays are specially designed with the spray box external to the pipe; liquor being fed to an annular chamber, and then direct to the spray nozzle. By shutting-off the liquor from the pipe supplying the annular chamber, and opening a cock at the back of the spray box, direct access is given for cleaning. The sprays are easily accessible from the platform running on the top of the bench at the back of the foul main (see figs. 25 and 26).

The 4-in. connections from the seal pots are connected to tar and liquor separating tanks set opposite the centre of each bench, by means of 6-in. tar and liquor mains provided with large inspection covers, for cleaning purposes.

FIG. 21.—CONGDON STANDPIPE, SEAL POT, VALVE PLATES AND LEVER.

FIG. 22.—RETORT BENCH, CHARGING SIDE.

The 4-in. downtake pipes are immediately opposite the buckstays, and, therefore, do not in any way interfere with access to the regenerator flues.

The tar and liquor separating tanks are 17 ft. 6 in. long, 8 ft. wide, and 5 ft. 6 in. deep, divided into three chambers with baffle plates in each. It has been found since the plant started working that these are of ample capacity to ensure complete separation of the tar and liquor; no tar being found in the last, or liquor, suction chamber. Liquor pumps are provided in duplicate for pumping the liquor over the standpipes; and as the cellar floor is below ground-level, tar pumps are also provided for pumping to the wells the tar run-off daily from the separating tanks.

The scheme provides for two waste-heat boilers. The first boiler is situated at the end of the new extension, and is of sufficient capacity to deal with the waste gases from nine settings. The boiler is of the Spencer-Bonecourt "Kirke" patent type, 8 ft. in diameter by 17 ft. tube length, suitable for a working pressure of 100 lbs. per sq.in., with a superheater capable of giving a superheat of 100° Fahr. A second and larger waste-heat boiler is to be installed of sufficient capacity to deal with waste gas from the sixteen settings in course of construction in the existing retort house. The main flues of all three benches

are inter-connected, and provided with dampers, so that by the operation of these dampers it will be possible to work the waste-heat boilers at their maximum capacity at all times. This was considered to be desirable, as it is the ultimate intention to utilize the waste-heat boilers for the generation of electricity for the whole of the power to the works.

Provision is made in the scheme for two external producers for the gasification of coke breeze or cheap slack, each having a capacity of 12,750,000 B.Th.U. of gas per hour, which will be sufficient for the heating of twelve settings. The producers are to be erected beneath the extension of the coal telpher; and the overhead coal bunkers supplying slack or coke breeze to the producers are to be fed by the telpher machine grab.

On the discharging side of the house an electrically-operated coke bus (see figs. 6 and 27) is provided for feeding coke direct to furnaces or to telpher skips from the top tiers of retorts, whereby labour is saved and breeze formation prevented. The coke is removed from the house by a high-speed telpher machine on to an external quenching bench provided with sliding doors for the discharge of the coke, after quenching, into a receiving hopper feeding a coke breaker and elevator, whence it is taken to overhead screens and storage bunkers. Provision is also made

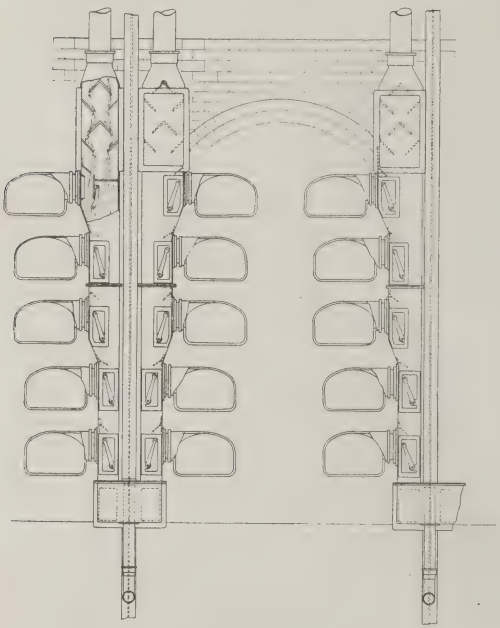

FIG. 23.—DETAILS OF IMPROVED CONGDON STANDPIPE.

for a quenching tank fitted with hinged doors at ground-level at the gable end of the house. These doors are closed by the weight of the skip and opened by counter-weights; the doors being arranged to close before the skip actually touches the water in the tank. A special steam duct from the tank carries the steam away above the level of the retort house. This arrangement is designed to prevent nuisance from the diffusion of steam and coke breeze which arises when quenching is carried out in an open tank.

The telpher track is carried round the coke storage yard to form a continuous loop, so that the telpher machines will travel in one direction only when in operation (see fig. 1). It may be mentioned as a point of interest that the existing coke telpher track has been utilized as far as possible; the foundations of the trestles being increased in height to raise the track to the new level.

A retriever pan-ash washer is installed on the discharging side of the retort house extension, the elevator supplying the washer being carried from cellar floor level. The apparatus is also arranged for feeding from ground level for the purpose of breeze washing.

The stage-floor in the retort house is carried separately from the bench, so that no expansion can be transmitted to the house framing; and chequered plates over the intervening space between the floor and the bench are constructed in a manner to allow an air space to assist ventilation beneath the floors.

The retort house extension containing the first new bench of nine settings is a steel-framed building filled with 9-in. and 4½-in. brick panels. The chequered brickwork panels for ventilation on the sides and gable end are arranged as lettering to form, at the sides, an advertisement reading "Use Gas and Coke," and, at the gable end, "Use Gas." (See fig. 4.)

Construction.

The foundations for the whole of the plant were laid down by the undertaking, employing direct labour. The subsoil is loam and sand to a depth of 6 ft., when a water-bearing gravel bed of 7 ft. thickness is reached. This overlies a stratum of blue clay, which, it is presumed, in turn overlies the red sandstone formation. The depth of this latter has not been proved on the site.

It was not possible to take the foundations down to the clay, on account of the cost; and it was decided to construct the bench foundation as a reinforced concrete raft above the gravel bed—the main bearing points of the raft being the stanchion bases, and the pier walls of the retort bench. Grip steel bar reinforcement was utilized; and fabric reinforcement in flat sheets covers the whole of the bottom of the foundation, in order to disperse over the whole area the portion of the load distributed between the 18-in. pier walls of the bench. Distribution of the load from the end and side stanchions and 18-in. piers is ensured by continuous beam reinforcement alternating from the top to the bottom of the foundation, according as the bending moment is positive or negative. Particular attention was paid to the ash-pan pockets, which were specially reinforced with ⅝-in. stirrup rods, to distribute the load. In no case does the whole of the loading on the ground exceed two tons per sq.ft. The average thickness of the concrete foundation is 2 ft.; and by the method of reinforcement adopted, greater strength is obtained than could have been secured by massed concrete, and at much less cost. The pipe trenches formed in the foundation to receive the gas mains for the supply of fuel gas to the settings have special fabric reinforcement.

The erection of the new benches in the existing house required the deepening of the cellar floor to the extent of 4 ft., to provide for the deeper settings; and this necessitated the breaking-up of the existing massed-concrete foundations, 4 ft. in thickness. For this purpose hydraulic cartridges were used; the method of operation being to drill a hole 5 in. in diameter in the concrete, and insert a hydraulic cartridge, which consists of a steel cylinder, 18. long, containing four plungers which can be expanded 2½ in. from the circumference of the cartridge. The cartridge is wedged in the hole by steel wedges driven in front of the plungers, which are extended by hydraulic pressure supplied by hand through a screw pump until a fracture in the bed of concrete is made. The maximum pressure exerted by one cartridge is 400 tons.

The large blocks of concrete were afterwards broken-up by means of pneumatic picks operated by compressed air. The cost of demolishing the concrete foundations by this means worked out at 22s. 6d. per c.yd.

The contract for the whole of the work, with the exception of foundations, stoking machine, and improved Congdon standpipes, which were supplied by Messrs. Aldridge & Ranken, Ltd., of Bath, was let to Messrs. Robert Dempster & Sons, Ltd., Rose Mount Iron Works, Elland, on March 19, 1924. The work on the foundations for the retort-house extension was commenced on March 20, 1924; and these were completed ready for the contractors in the space of twelve weeks.

The steelwork framing of the retort house, stage floors, stanchions, and retort-bench bracing, amounting in weight to 220 tons, was erected complete in 57 working days. The whole of the work on the extension, including the building of the retort benches and construction of the steelwork telpher track superimposed on the reinforced con-

crete telpher track between the canal and the grab pit, was completed by Nov. 26, 1924, and gas-making was commenced on the new plant on Jan. 10 of this year. The difficulties of construction were accentuated by the fact that the existing retort benches had to be worked to their maximum capacity until the extension of the house was completed.

WORKING RESULTS.

The first new bench of nine settings has been in operation for a period of four months; and some interesting data have been obtained of the working results. The settings have so far only been worked with their own producers, as it has not been possible to attempt coal-gas firing, owing to the reconstruction in progress and sufficient plant not being available. Further, the external producers have not yet been erected. The results, however, prove that the setting working with its own producer is highly efficient.

The following figures are the result of a six days' experimental run :

Duration of charges	12 hours
Coal carbonized	710·4 tons
Gas made	9,896,000 c.ft.
Make per ton (corrected)	14,360 c.ft.
Average calorific value	529 B.Th.U.
Therms per ton	75·96
Coke made	497 tons 6 cwt.
Coke used on producers	70 tons 19 cwt.
Coke available for sale per ton of coal carbonized	12 cwt.
Coke consumed on producers per ton of coal carbonized	2 cwt.

The average analysis of gas made during the period of test is as follows :

	P.Ct.
CO_2	3·4
O_2	0·4
C_nH_m	2·0
CO	10·0
CH_4	26·3
H_2	51·0
N_2	6·9

Average total inerts, 10·7 p.ct.

The coals used were a mixture of slacks, all under 1 in. screened size, drawn from Lancashire and Yorkshire seams; the proximate analysis being as follows:

	P.Ct.
Moisture	3·3
Organic volatile matter	30·0
Ash	11·0
Fixed carbon	55·7
Total	100·0

The average coke consumption on producers is 10 lbs. of coke per 100 lbs. of coal carbonized. The coke produced was of good-grade quality of fine-close to medium-close structure, and hard; the average ash content being 15·3 p.ct. The heat balance on the basis of the above trial shows a net efficiency of carbonization of 82·04 p.ct.

Careful observations were taken over a period of eight weeks, to ascertain the heating efficiency of the settings; readings being taken with a Siemens optical pyrometer. During this period the settings were on 12-hour carbonizing, operated in two 8-hour shifts, and 4-hour periods between charging. The normal weight of charge was 16 cwt.; and with regard to this item, it should be pointed out that a large portion of the coal used consisted of washed fine slack, which does not flow so easily through the hoppers and stoking machine as dry slack. When working on the latter, an average charge of 17 cwt. can be maintained.

The average temperatures maintained in the combustion chambers on the nine settings throughout the period of eight weeks are as follows:

	Average Temperature, °C.
Setting No. 1	1253
,, No. 2	1287
,, No. 3	1285
,, No. 4	1286
,, No. 5	1295
,, No. 6	1293
,, No. 7	1296
,, No. 8	1301
,, No. 9	1278

These temperatures are not high, but were more than sufficient to ensure complete carbonization within the period of twelve hours.

To ascertain the temperature gradient within the settings, daily readings were taken at various points, of which the following is a summary:

Points where Readings were Taken.

A. . . . . Combustion chamber.
B. . . . . Top of the settings, at a point where the gases divide above the top tiers of retorts.
C. and D. . . Left and right sight holes under bottom tier of retorts above waste-gas flue.
E. . . . . Temperature of waste gases in the main flue.

—	A.	B.	C.	D.	E.
Max., °C.	1370	1017	955	940	620
Min., °C.	1230	940	815	847	460
Average, °C.	1302	988	900	905	538

These figures are interesting in that they show that the balance of heat throughout the settings is well maintained. The average CO_2 content of the waste gases is 16 p.ct. There is a slight excess of oxygen; but this does not reach 1 p.ct. These figures substantiate the good fuel results obtained. The producers work without need of clinkering, and easily maintain the temperatures with the combustion chambers under pressure.

The standpipes have so far proved most satisfactory in operation. The provision made to meet expansion proved to be adequate; and though in some instances the forward movement of the front wall of the settings, due to expansion, was as much as $\frac{3}{4}$ in. horizontally and 7-16 in. vertically, in the case of the top retorts, this was easily met by means of the suspension adopted and the spherical sleeve connections between the mouthpiece and standpipe sockets. When opened up for examination, the standpipes showed a slight film of tar about $\frac{1}{32}$ in. thick covering the sides and valves.

Equal conditions as to pressure are easily maintainable on all retorts; the retort-house governor being worked with approximately $\frac{1}{10}$ in. vacuum on the inlet. On opening the valves when charging, it is observed that the gas is practically in a state of equilibrium. The pressure maintained on the delivery side of the liquor pump is 10 lbs. per sq.in.; and the liquor is delivered through the sprays to each standpipe at the rate of 5 gallons per minute. There is an automatic relief valve on the liquor delivery pipe, returning the excess liquor to the separating tank.

Daily observations of the temperature of the liquor in the standpipe seal pots and outlet of the separating tank have been taken at 10 a.m. and 4 p.m.; and in this connection it should be pointed out that the shift hours when charging takes place are from 10 a.m. to 6 p.m., day and night shifts.

The following are the average temperatures over a period of eight weeks:

—	Time.	Max.	Min.	Average.
		°Fahr.	°Fahr.	°Fahr.
Seal pots	10 a.m.	191	151	181
	4 p.m.	199	181	190
Tank	10 a.m.	170	154	163
	4 p.m.	183	168	178

The cooling of the liquor in its passage through the separating tank varies on the average from 18° Fahr. at the commencement of the charging period to 12° Fahr. at the end. The average temperature of the gas leaving the standpipes is 179° Fahr. at the commencement and 199° Fahr. at the end of the charging period.

It will be observed that the difference between the gas and liquor temperature is only 16° to 21° Fahr. It is noticeable, however, that even with this difference a considerable amount of shock cooling and scrubbing effect is obtained. During the trial run of six days, previously referred to, the tar drawn from the settling tank was measured, and was found to be equivalent to 49·04 lbs. per ton of coal carbonized.

The loss by evaporation is made up by the constant addition of fresh water to the separating tank, and the ammonia content of the liquor in circulation remains at a constant strength averaging 11·6 ozs. The distribution of ammonia as between fixed and free is as follows:

Fixed	11·2 ozs.
Free	0·4 ozs.

This is easily accounted for when temperature conditions are taken into account. The fixed ammonium salts contained in the liquor are largely ammonium thiocyanate; and the action between sulphuretted hydrogen and hydrocyanic acid is continually adding to the content of this compound. Sulphurous acid, sulphuric acid, and thiosulphuric acid are present only in very small proportions.

The work on scrubbers and washers has been greatly relieved; and it has been found that a large percentage of the free ammonia is brought down in the condensers.

With regard to the effect of the standpipe system on the sulphur content, the following figures are of interest:

April, 1924.	Average H_2S content on the inlet of purifiers	749 grs. per 100 c.ft.
April, 1925.	Average H_2S content on the inlet of purifiers	594 .. .. ..

The average decrease was 155 grains per 100 c.ft., or 20·7 p.ct. on the 1924 figures. The same class of coals were carbonized in both periods; the average sulphur content being 2·55 p.ct. on dry coal basis.

It is interesting to observe that in the old retort house there were two ascension pipes per retort, whereas the standpipes are on one side of the new bench only. Previous experience has been that H_2S in gas from horizontal retorts with one ascension pipe is higher than two. The lower sulphur content with the standpipes is doubtless due to the effect of ammonia washing.

The period of operation of the plant has not been sufficiently long to permit of the collection of accurate data with respect to the yield of the liquid products; and in giving the foregoing results, the author has confined himself specially to the results bearing most directly on the new features which it has so far been possible to record.

Discussion.

The President: We have heard a most instructive engineering paper on carbonizing and the reconstruction of a gas-works. I have had the privilege of seeing these works, not since they were completed, but during the time they were in progress; and I can only say that Mr. Carr is to be congratulated on being able to take a plant which required considerable modification and utilize it so as largely to increase the output. He has had a difficult task at Stretford, because, as you have heard,

Stretford is an intensely industrial area, and the increase in the demand for gas was very considerable. Therefore Mr. Carr is to be congratulated on being able to reconstruct these works, and also supply a greatly increased demand. You all remember that his father, Mr. Isaac Carr, was noted as being the one who supplied the cheapest gas in the world. I venture to say that Mr. W. M. Carr is following in the footsteps of his father. The figures he has given us show the efficiency of the plant that he has introduced, and he has also adopted some very novel methods with reference to carbonizing. I am sure there is a fund of matter in the paper which would probably take us a day if we were to discuss it adequately; but I should like one or two of those present to enter into the discussion. Any questions that you may care to put, I am sure Mr. Carr will be pleased to answer. As Mr. Toogood has been mentioned in connection with the plant, perhaps he will say a word or two.

Mr. H. J. TOOGOOD: As a visitor, I appreciate very highly the permission to say a few words in connection with this contribution. First of all, I must congratulate Mr. Carr upon a very splendid paper. It is crowded with most interesting facts. As many of you will be aware, the chief reason for my connection with the Stretford installation is that Mr. Carr, when he selected his scheme of carbonization, elected to place his order with the firm of Messrs. Robert Dempster & Sons, whom it has been my privilege and pleasure to serve for the past 21 years. During this long association it has been my lot to be connected with various forms of carbonization. So that there shall be no misunderstanding, I would just like to say that in 1904 I was chiefly engaged on stoking machinery; in 1908 I was engaged on intermittent vertical retorts; in 1911, with continuous retorts; and now I stand on the platform with horizontal retorts. But I do not want you to think that there has been any variaion whatsoever, inasmuch as the consistent theme running through the whole of that experience is the development of the machinery of carbonization; and it is under the head of the development of the machinery of carbonization that I venture to discuss Mr. Carr's paper. As Mr. Carr has headed his paper "Selection, Design, and Construction of New Carbonizing Plant at Stretford," I venture the opinion that the lesson of this paper will be remembered for many years as "cheap gas, and how to get it *via* residuals." As an example of this, I would mention Mr. Carr's father, Mr. Isaac Carr, whose name is brought to mind by the very mention of the words cheap gas. The author of this paper has, metaphorically speaking, been reared in an atmosphere of cheap gas; and he will therefore be a champion, second to none, of cheap gas.

In reading the paper, one is struck by the bed-rock principle which underlies the whole of the reasoning—viz., to keep the net cost of coal as low as possible. Consequently the lay-out of the works is really very unique. Mr. Carr did not mention destruction in the title of the paper; but in order to get the plant of his heart's desire, he has had to destroy a considerable amount of good work. Now you will see the theme. He has had to get a retort house wedged between the railway and the canal; so that the widest possible fields for the purchase of cheap coal are, as it were, brought to the door of his retort house. The actual plant is described at length in the paper; but I would like to express it from my own point of view. He has chosen a 70 ft. high-level telpher; and the arrangements are such that he can check the coal from the canal or from the railway or from stock. Though he may have coal from a hundred sources, and cheap coal, the mixture that gets into the retorts is a desirable blend, and he gets coke which is consistently good for his Stretford coke market. Under this head, I suggest that Mr. Carr's paper is quite eligible for the Coke Competition organized by the Editor of the "GAS JOURNAL." Mr. Carr has explained the difficulties at Stretford when this plant was being considered, the chief of which was that the plant must be working for the winter. Therefore, there was very little time to design it. Moreover, the coal to be carbonized was slack; and as the plant had to be working for the winter, Mr. Carr laid it down that there must be nothing of an experimental nature. Nevertheless, the Stretford coke market was always in evidence as being a primary feature in the production of cheap gas; and therefore it was realized that, if the net cost of coal could ever be brought down to nothing, then many economic factors in gas manufacture would be turned topsy-turvy. It was to seize upon this opportunity that Mr. Carr decided to go forward with optional gaseous firing.

Being partly responsible for the design of a portion of this new setting, I would, with your permission, just like to run through its salient features. With regard to the retorts, these have been designed to carbonize slack which is sometimes wet and sometimes dry; but there is always a heavy charge to be carbonized in regular time periods. It was expected that we should have to go to higher temperatures of carbonization; and therefore 95 p.ct. silica retorts were adopted. That these retorts are gas-tight, and that they do their work well, is borne out by the 75 therms per ton of slack with a 10 lb. fuel consumption. The side walls of the retorts were likewise 95 p.ct. silica bricks; the idea being that the retorts would live when the expansion of the silica gave, so to speak, an even keel, so that the gas-tight qualities of the retort should not be disturbed. A space of 2½ in. was allowed on the top of the wall under the crown of the arch on account of this upward expansion; and this space has been virtually absorbed, thus bringing out a fact, never known before, that silica structures expand considerably more than does a solid silica brick when tested in a muffle in a laboratory. To absorb the side expansion of silica walls is much more difficult, as it must be absorbed within the one arch of the setting. Otherwise it would be cumulative down the side, and consequently, in long settings, would be disastrous. To prevent this, the side walls were saw-toothed or staggered. This prevented any squat and consequent leak. No timber was used, for the simple reason that timber burns away at one period; and therefore, since silica expands over a long period, it was felt that timber would leave a space, and a space within a structure like a setting, to say the least, is an unknown quantity, which we were better without. As regards heat transmission, Mr. Carr has said that the walls are 6 in. thick, and the flues 11 in. wide. This means that 60 p.ct. of the retorts are exposed to rapid heat transmission, which has turned out to be effective by the very low fuel consumption. As regards the producer, we believe that the producer is the driving force of any setting, and therefore too much attention cannot be given to its design. But we had a narrow arch with which to work, and we had to put in extra regeneration; yet we wanted a large producer. By scheming the regenerators and utilizing the full depth of the solid brickwork, some 12 ft., we were enabled to get in a producer of 26 sq. ft. area. The grate for this producer was on the screen-bar principle, which has not been in evidence for more than three years. To those who have had no experience of how this type works, it will come as a revelation to witness it in operation. With a smooth, steep perforated screen, such as in the screen-bar grate, the coke slips completely down; whereas with a step grate the coke tends to rise at every step. With a screen-bar grate, the coke continually creeps downwards, while the ash gravitates from the pan. With regard to the regenerators, for the purpose of fuel consumption you cannot have regenerators too large; but here, as I have said, we had only a small space, and therefore the settings consist of a nest of tubes. There are no flues other than tubes. The waste heat descends the centre row. Each of the tubes in the centre row opens to the outside wall; consequently, each being 12 in. by 9 in., you can examine it and clean it and repair it. The secondary air on coke firing passes up through the outside pairs of tubes. The excess air passes up the second pair, and the excess fuel to be preheated passes up the tubes near the walls. These tubes form a very thin division between the waste heat and the secondary air, and consequently are economical in heat transmission, and yet give a double safeguard to preserve efficiency.

Mr. H. H. COLLETT (Sheffield): I heartily congratulate the author on having given us a paper which contains a tremendous amount of food for thought; and I am sure we shall all study it at our leisure, because it is a little difficult to discuss it off-hand. We can then adopt his principles if we are so inclined, because a great amount of ingenuity has been displayed. With regard to the silica retorts, I should like to know whether they are made of 95 p.ct. silica throughout—*i.e.*, whether both the arch and the floor are of 95 p.ct. silica. Then with regard to the liquor circulation. I take it, from what Mr. Carr says, that the liquor which comes from the Congdon standpipes flows down into a tank, and is pumped over again. The temperature of that liquor is very high, and I should like to ask if there has been any trouble with this high temperature. I remember in Leeds we circulated liquor in a similar manner, and got a result, on analysis, very similar to that of the author. It was very high in fixed ammonia and low in free ammonia; but we certainly had trouble with the wrought-iron pipes through which the liquor was sent, and considerable trouble with the pumps. The piston rods had to be renewed fairly frequently, owing to the very corrosive effect of this liquor, which was high in chlorine. I must join issue with Mr. Carr with regard to the quenching of the coke. From my experience, I do think that quenching coke in telpher skips by dumping it into tanks is a bad thing; and I am sorry that Mr. Carr has adopted what I should regard as a retrograde step. Personally, I think the quenching of coke can be very much better done in front of the retort benches by means of hoses. We do that in Sheffield. It is very satisfactory, and we are very seldom troubled with coke fires. In fact, during the whole of last winter, we did not have a single coke fire or the suspicion of one on the heap. I am very pleased to see Mr. Carr speaks so highly of the Congdon standpipe, particularly as I have heard not very good reports of it. Mr. Carr has given us a good report, and no doubt this is due to the modifications which he has so ingeniously applied to it. There is just one other question. What gas is Mr. Carr supplying in his district? Is he supplying a straight 520 B.Th.U. gas, or is he diluting it with water gas? That is an interesting point I should like to be clear upon.

Mr. W. B. LEECH (Gas Light and Coke Company): As one of the judges in the Coke Competition, I would like to warn Mr. Carr that he is already disqualified. [Laughter.] I should like, however, to add my thanks to him for this excellent paper, because I am sure it will be appreciated by all the members, and especially those engineers who are contemplating extensions to their carbonizing plant. The selection of new carbonizing plant is always a difficult problem, each type having so many points in its favour; and certainly I have always found it a very difficult thing to arrive at a really satisfying decision. Mr.

Carr seems to have threshed the matter out, and certainly from his paper I am obliged to agree with him that horizontal retorts are better than any other type for his particular purpose. In fact, I am very much in agreement with him all through, with the exception of one or two small matters. Perhaps I might mention the section of the retorts. I notice Mr. Carr has gone in for 24 in. by 18 in. We have had rather long experience of this type at Beckton, but have found they are rather on the large size for our class of coke. We have many 22 in. by 16 in.; and while it is difficult to say there is an advantage in this size, we find them easier to work, and fancy the coke is better. We also imagine that we get more therms. We have been making experiments recently, and have set up in one of our houses a 24 in. by 18 in. and a 21 in. by 15 in. retort; but I cannot give you results, because we have had a little trouble with the hydraulic main. However, a very interesting fact has shown itself. Both these retorts are charged with a projector type of machine, and as there is no free space between them they are at the same temperatures. Yet the free carbon in the tar from one retort is double that from the other. With regard to it not being wise to work at temperatures from 1325° to 1350°, we work for long periods up to 1400°, and have not noticed any effect upon the setting. Therefore I should like to know what reasons the author has for setting a limit to the temperature. I notice his setting is designed with a special combustion chamber arch to prevent the lifting of the combustion chamber arch itself and the walls of the retorts. We have had rather a strange experience. Previously our trouble has been through the expansion of the silica lifting the centre portion of the walls, and raising the inner side of the retorts, sometimes to the extent of 4 in. or 5 in. Since the silica brick manufacturers have been put on their mettle, they have apparently got a better material or better processes, because in our new settings we have found exactly the opposite effect. We have had a slight settlement, probably due to the expansion joints or timber which we have put in. I would like to congratulate the author on his installation of Congdon standpipes. Our experience at Beckton is not in their favour; but I think I have said before that this is due to the length of the connection between the mouthpiece and the standpipe. The design shown by the author, I should think, would be an excellent one, and I am really very sorry it was not available some years ago when I recommended them. I should like to mention that the design which I showed in 1919 is hardly representative of the type they use in America. I was over there in 1920, and they certainly did not use that type of Congdon pipe then. It seems that I have used a very old one; and it is hardly fair to the American engineers to compare the new type with the old type. I do not think the author of the paper has said quite sufficient about the coke plant. Coke, as everybody knows, is troublesome to handle, and we should like a little more detail as to how the plant is designed. I have always been led to understand, and my experience has shown me, that telpher plants for an installation of the size of the author's are on the slow side. Perhaps he has arranged for two telpher drivers, or he may have some other means for speeding-up. Will the author give us the cycle of operations, and also some idea of the cost of handling the coke?

Mr. R. E. Gibson (Liverpool): There are just two points I would like to mention. I congratulate Mr. Carr on the splendid results he has obtained with the use of slacks. At the same time, if we all went on to slacks I am afraid there would be no advantage in their use, because the price would probably go up to that of screened coal. Moreover, the throughput is bound to be reduced where slacks are used. The results at Stretford are very remarkable, and reflect great credit on Mr. Carr and his plant. I notice he has made special provision for the use of coke breeze in his producer. This may be suitable to the local conditions; but at Liverpool we have no coke breeze at all. We have plenty of coke, but no coke breeze; and therefore such furnaces as those at Stretford would be useless to us. I am sorry that this paper was not distributed before the meeting, because it puts one at a disadvantage in discussing it. The paper is full of interesting points which are worth careful study, and will undoubtedly help us very much in the future.

Mr. Thomas Hardie (Gas Light and Coke Company): I should like to add my thanks to those of the other speakers to Mr. Carr for his very interesting paper. The main point that struck me in listening to him was the extraordinary thoroughness with which he has studied the subject, and the care with which he has come to his decisions. He has considered all classes of carbonizing plant; and it is very interesting to-day to find an engineer who is prepared to consider all types. Many engineers seem to have got it into their heads that a certain type, whether it is one or the other, is their particular type under all conditions; and therefore I was very pleased that Mr. Carr examined so many types of plant before he came to a decision on the matter. I particularly wish to congratulate him upon using the Congdon pipe, and I wish to express appreciation of the thoroughness with which he has worked out the details of that piece of apparatus. The results he has obtained, I think, set us a new standard in horizontal retorts using slacks, and are such as we shall all be very anxious to reach. He has not explained it; but I think that the installation of the Congdon pipe is the possible explanation of these very fine results. The cooling of the gas as it leaves the retort, instead of it being brought up ascension pipes, has no doubt led to these important results. It has been an extremely valuable paper; and I am only sorry that Mr. Carr had to miss out any part in reading it. It is a pity we did not have the paper earlier, so that we could have discussed it more fully, though I feel that, from the thoroughness with which one can gather he has gone into the various details of the plant before he put it in, it would be rather dangerous to criticize merely on hearing it described this afternoon.

Dr. Parker: I should like to ask if the author has experienced any difficulty in getting the pitch out of the connecting piece between the mouthpiece and the standpipe, in the case of the Congdon pipe. Then the author mentions 40,000 c.ft. of straight coal gas as being the equivalent of a ton of coke. Owing to the large amount of excess air required to burn straight coal gas and also to prevent the deposit of carbon on the regenerator tubes, I think the figure should be more than 40,000 c.ft. Finally, would the author tell us where the samples of gas were taken?

Mr. S. Shadbolt (South Bank): I should like to congratulate the author on the thoroughness with which he has gone into this matter. Of course, the usefulness of these papers is largely found in their application to districts having similar circumstances to those of the author, and in the present case I imagine we must take it that considerations of the conservation of our coal supplies did not trouble Mr. Carr. There is a good deal in the point made by Mr. Gibson, that many of us cannot burn these slacks even if we could get them cheapiy. Nevertheless, I think we shall all congratulate Mr. Carr on what he has done.

Mr. H. Davies (Chesterfield): As one representing a small gas-works, I must say that Mr. Carr's results are certainly extremely good. I have had the opportunity of installing similar plant to Mr. Carr's and operating it for the past six months; but I must confess that I have never been able to get the figures that he has mentioned in the paper. I should appreciate it if Mr. Carr would give me the privilege of going over the Stretford works and seeing how he does it. I am always willing to learn. With regard to the charge of 16 or 17 cwt. when using these retorts with slack, it seems to me that the charge is rather large, and must cause some difficulty in discharging. I should like to know whether the author has any difficulty in that respect, with consequent damage to the retort. With regard to the liquor, at 120° one must naturally expect some loss; and I should be glad to know whether this has been Mr. Carr's experience. He has only had four months' experience; but perhaps he will be able to give us some information on that point.

The President, in closing the discussion, said that, on account of the late hour, he would ask Mr. Carr to reply on the following morning.

Mr. Carr: I desire to thank you for the very kind way in which you have received my communication. Mr. Toogood, who opened the discussion, dealt generally with the matter of design; and one point which he emphasized—and with which I think we shall all be in agreement—was that, in order to ensure low fuel consumption, the producer in the first instance must be of large capacity, and that the regenerators cannot be too large. That, of course, was a factor which had an influence on the design of the settings, and, I believe, was a great factor in the results obtained up to now, so far as fuel consumption is concerned. Mr. Toogood also referred to one of the main objects being to bring as low as possible the net cost of coal. This was aimed at, of course, from the outset, and in the arrangements for gaseous heating the factor was that these arrangements should be available if residuals were a strong market. Of course, if coke is a weak market, obviously it pays to heat the settings with their own producers, utilizing the coke, rather than use gas from extraneous sources, whether it be producer gas or coal gas.

Mr. Collett asked if the retorts were 95 p.ct. silica throughout. That is so, and I think it is mentioned in the paper. With regard to liquor circulation, also mentioned by Mr. Collett and other speakers, the temperature of the liquor is admittedly high; and I might say in this connection that I think better results would be obtained if the liquor were cooled to a greater extent. In the other separating tanks which are now being put in, arrangements are being made to pass the feed water for the waste-heat boiler through a heater situated in the tank to serve a dual purpose—viz., to preheat the water for the waste-heat boilers and to cool the liquor. I think by this means it will be possible, instead of having a difference in temperature of the liquor leaving the standpipe—*i.e.*, till the point it is pumped from the separating tank—of 18° Fahr., we should get a difference of something like 35° or 40° Fahr., by cooling in the separating tanks. In that way we should get shock cooling to a greater extent than we do to-day, and a better scrubbing effect. No difficulty has been experienced in pumping the liquor at 170° or 180° Fahr. The pumps are of the ordinary Evans "Reliable" type; and though they have only been working for six months, they have shown, up to the present, no sign of deterioration. Mr. Collett also raised the very important point of the quenching of the coke on the floor. In my hurry yesterday I probably did not explain clearly what the arrangements really are. The way in which it is intended to deal with the

bulk of the coke is to pick it up with a high-speed telpher, and discharge it into a coke quenching bench situated outside the retort house, having done a preliminary quenching by hose as the coke is pushed-out from the retorts into the telpher skip. The telpher will not wait, but will simply discharge one skip and then return for the next skip. That is the intention; but this part of the scheme is at present only under construction, and at the moment we are quenching temporarily in a quenching tank, because in order to maintain the supply of gas the work had to be carried out in two stages. The first stage was the extension of nine beds, and the second stage the reconstruction of two beds of eight retorts in the existing house; and we cannot use the new coke arrangements until the reconstruction is finished, while the reconstruction could not be carried out until the nine beds are completed. The President has just referred me back, and asks what I mean by a high-speed telpher. The normal speed of a telpher depends, of course, entirely on the gearing of the motor; and when I speak of a high-speed telpher I speak of a machine which, given a clear run, hoists and travels at the same time, which was not so in the case of many of our old machines. As soon as the skip is lifted off the floor, and is quite clear, the travel commences. I am afraid I cannot say what the actual speed is, because I do not remember.

Mr. TOOGOOD: What is meant by a high-speed telpher is not only that the speed of the telpher is 500 ft. per minute or more, but that the construction of the quenching benches in connection with the telpher is quite novel inasmuch as the telpher will pick up the skip at the bench, take it straight away, put it on the quenching floor, and come back again. Therefore the whole time of disconnecting ropes is saved. Hence this is a high-speed telpher—about twice the speed of working of the usual telpher.

Mr. CARR: Thank you. The next point is with regard to dealing with the coke on the quenching bench. When the coke is discharged on to this, there is an automatic lifting bar; and on the return of the telpher for the second load of coke, the bar will be automatically lifted, and the coke will be discharged into the hoppers which supply the coke elevators. It has yet to be proved that the speed of operation will be adequate, having regard to the size of the house, with one telpher machine. The period within which we hope to complete the cycle into the house, discharging and back again, is 1 min. 20 sec. That is what we are aiming at; but I wish to make it clear that that is an estimate of what we hope to do, and is not a figure which we have achieved. A further question by Mr. Collett was as to the quality of the gas we are supplying. We supply 500 B.Th.U. gas at the moment, and it is our intention to declare that. We are diluting with water gas for this purpose; but it is possible that, when the whole of this extension is completed, we may declare a higher calorific value. That, again, depends largely upon the commercial circumstances at the particular period.

I am very pleased to hear from Mr. Leech's very kind remarks that he agrees with me that horizontal retorts were the right thing for Stretford. The section of the retort, 24 in. by 18 in., was chosen as being, in my opinion, the most suitable. We had retorts at Stretford 21 in. by 15 in. The old retorts were that size, and they were 20 ft. long; and so far as our short experience has gone, there is absolutely no comparison which could be made in results, because there are so many factors in the new plant which did not exist in the old. But I think with a simultaneous machine such as we have, as distinct from the projector type of machine, the 24 in. by 18 in. section is the most suitable; and dealing with Lancashire and Yorkshire coals, I venture to think it is the most suitable size, even for the projector type of machine. Mr. Leech said he could not give us the comparative figures for retorts of 21 in. by 15 in. section and retorts of 24 in. by 18 in. section. That is, of course, a difficult matter. If we had the two sections, both with standpipes, the figures would be very illuminating. One advantage of the standpipe is that it is a very simple matter to take samples of gas representing a period of carbonization when you have five retorts connected to the same standpipe. Another point raised by Mr. Leech was with regard to the free carbon in the tar. As long as the charges are maintained and the carbonizing period is not too drawn-out, we can keep it low. The free carbon in the tar is, of course, less when working on the eight-hour carbonizing period than it is with the twelve-hour period, when we have a higher temperature following the tailing-off in the last four hours of carbonization. Mr. Leech also raised the question of the coke plant, which I have already dealt with, except that I want to make it quite clear that the quenching tank is provided for use only in an emergency when the quenching bench or the mechanism in connection with it is out of operation. I want that to be clearly understood, because I think it is generally agreed among all gas engineers that immersion of coke is not at all desirable in any circumstances. I cannot reply to Mr. Leech's question as to the cost of handling coke, because the scheme is not yet completed.

Mr. Gibson mentioned the fact that we could not all use slacks, as the price would then probably go up to the price of screened coal. I appreciate that the price of slack would undoubtedly go up very considerably if it were extensively used by gas undertakings. At the same time, I do not quite agree with Mr. Gibson that it would go to the price of screened coal, because, after all, the kind of slack which is bought by myself, for instance, is from coal that is not being sold to gas-works, but is slack which is on the market from household fuels and other fuels. Mr. Gibson referred to the fact that the throughput was reduced if slacks are used. That, of course, is true in a measure. I would estimate the reduction in the throughput, using half-inch slacks as against large coal and nuts, as being approximately from 8 to 10 p.ct. Mr. Gibson also said that they were fortunate in Liverpool in having no coke breeze. This, again, I appreciate. When the coke leaves the retort house there is no breeze; but I would, with all respect, say to Mr. Gibson that, if he has a few thousand tons of coke in stock, there must be some coke breeze when that stock is moved. Even if he is making coke as hard as furnace coke, he will make some breeze when he moves the stock. There are times when we all of us must have some coke breeze; and the intention of the separate producer is not only to use coke breeze, but to use the cheap slacks containing up to 30 p.ct. of ash. There is a large quantity of slacks—almost colliery waste, you might call it—lying at the collieries to-day, which can be purchased very cheaply by those undertakings situated in the vicinity of the collieries; and this particular producer, with the super-imposed retort, is specially designed for the purpose of utilizing such slacks as producer fuel. These slacks can be bought, for instance, delivered at the Stretford works, at 7s. or 8s. per ton, and that is undoubtedly an economic factor. Even if coke is only worth 14s. a ton, and you can use cheap slack in your producer at 7s. or 8s. per ton, there is a great economy to be effected in heating. I refer, of course, entirely to the Stretford circumstances, and works similarly situated. To show it is being successfully done, I would refer you to the work with this super-imposed retort at the works of the Portland Cement Manufacturers at Swanscombe, and also to the experiments which I myself carried out at Preston. I have here a sample of the coke made in the passage through the retort of a Scotch washed fine at the works of the Associated Portland Cement Manufacturers. Here is a sample of the fine slack that was passed through, and here is a sample of the producer fuel that was made from it. This slack has a fairly high ash content—over 20 p.ct.—and the producer fuel was, as you will see, coked to a very good degree. The period of the passage of the slack through the super-imposed retort is not more than 40 or 50 minutes; and the temperature at which this coke is produced is approximately 500° to 550° Fahr. That is the average temperature in the retort. I explain it by two things—first, direct heat transference; and, secondly, the mechanical action of turning over the particles of coal in contact with the heat. It does, I submit, become a factor which is worthy of the consideration of those undertakings situated in close proximity to the coal supplies, where this very cheap coal can be obtained, of gasifying such cheap fuels for the purpose of heating the retorts, provided it can be successfully gasified. I should like to make it clear that on this matter I am now speaking of what has been done elsewhere, and of what I hope to do at the Stretford works.

Dr. Parker had asked if there was any difficulty in getting the pitch out of the connecting-piece between the mouthpiece and the standpipe. It is only 7 in. from the inside of the mouthpiece to the face of the valve; and the retort house lid-man has a small auger at an angle which he inserts into the opening of the valve, and moves up and down. There is no difficulty in getting them absolutely clear. The standpipes are arranged with the seal pots on the stage floor level, and are cleared out at each shift by the lid-man, who goes round and simply fishes to see if anything has been pushed through. We get about half a bucketful of mainly a mixture of carbon; but we have had no signs of pitch. It is a mixture of carbon and thick tar; but up to the present we have had no signs of pitch in the working of the standpipes. Another point which Dr. Parker raised was with regard to the figure I put forward of 40,000 c.ft. of straight coal gas as being approximately equal to a ton of coke; and he suggested that, with the excess air that would be required for the combustion of straight coal gas, and also to prevent the deposit of carbon on the regenerator tubes, a greater volume would be required. My estimate was made as the result of some investigations I was permitted to carry out owing to the facilities given me by the Chemical Company at Normanton, where they have been firing with coal gas for a considerable period, both preheated by regeneration and by admission direct into the producer arch below the combustion chamber. It was on the basis of the results of these investigations that I put forward this figure of 40,000 c.ft. I appreciate the difficulty which Dr. Parker mentions; and as a means of overcoming the question of carbon deposit, I think it will be probably necessary, on coal gas firing, to dilute with a certain proportion of either waste gas or, alternatively, with producer gas from external sources, because trouble has been experienced with straight coal gas firing through carbon deposit, as Dr. Parker rightly estimated. With regard to the samples of waste gas, these were taken at the end of the main flue, almost on the point of admission to the waste-heat boiler. The percentage of oxygen is low. We have had traces of CO in the gas, but only slight traces; and I put it down to the tightness and general efficiency of the new settings.

Mr. Shadbolt, in his remarks, suggested that the conservation of coal supplies was not a consideration of mine. I must rather

take exception to that. Possibly Mr. Shadbolt was looking at it from the point of view of gaseous therms; but there are, I suggest, two points of view. There is the point of view of maximum gaseous therms from a certain volume of coal, and the point of view of the maximum yield of both solid and gaseous therms. Both Mr. Shadbolt and myself—and, indeed, all of us—are aiming at getting the maximum yield; but Mr. Shadbolt takes the view that we will probably economize coal to a greater extent by getting the maximum yield in gaseous therms, and possibly I, being somewhat differently situated, do not quite see eye to eye with him. I will not delay the meeting now by giving the figures of the heat balance from which I showed an efficiency of carbonization of 82·04 p.ct.; but I will communicate them as part of the discussion. The only other point to be dealt with was that raised by Mr. Davies, of Chesterfield. I shall be very pleased to see him at Stretford, and show him what we are doing. With charges of 17 cwt. of dry coal evenly laid, we do not find the expansion on completion of coking has left a great amount of space at the top of the retort. We have had no trouble whatever in discharging; and I think that in these circumstances 17 cwt. charges are not excessive in 24 in. by 18 in. retorts.

The PRESIDENT: I am sure I voice the opinion of the meeting when I tender, on your behalf, our thanks to Mr. Carr for his very practical engineering paper. I feel specially indebted to him, because, when I approached him several months ago and asked him to write a paper on his new works at Stretford, he said he was very busy through having to meet a great increase in the demand for gas; but if it were my wish, as President, he would do it. He has fulfilled that promise to the utmost, and I personally thank him very much. On your behalf, too, I offer him our hearty thanks.

Mr. CARR: I thank you very much for the kind and patient way in which you have received the paper, and the reply to the discussion. I should like to say that I am indebted to the President in several ways. When the scheme first came under consideration of my Board at Stretford, another opinion was taken at my suggestion; and that "other opinion" was our President's. He supported the proposition I had put forward. I should also like to express my thanks to Mr. Toogood, who has co-operated with me in achieving what we have done—and I think we have realized some measure of success in this new setting. I should like to thank Mr. Ashley, of Messrs. Aldridge & Ranken, who assisted in carrying out various suggestions and modifications that we have made in the Congdon standpipe; while, finally, I should like to be permitted to express my thanks to my own staff, without whose help I could not have given this paper.

REPORTS RETAINED FOR PUBLICATION LATER.

This number of the "JOURNAL" is a complete record of the proceedings at the Annual Meeting of the Institution, in that an abstract of *all* the Papers and Discussions and the Verbatim Report of the sessions appear in it. We regret, however, that the unusual length of the contributions and discussions, coupled with postal restrictions, necessitates the holding-over of the following Reports: Wrought-Iron Tubing; Joint Refractories; Illumination Commission; and Gas Research Fellowship. It is our intention to include these as Supplements to our July numbers.

THE GLENBOIG UNION FIRE-CLAY CO., LTD.

Manufacturers of the highest grade of Refractory Fire Bricks, specially suited for furnaces subjected to the highest heats and sudden changes of temperature.

All Glenboig Goods are stamped with either "Glenboig" or "Star Works, Glenboig" Brands as under—

REGISTERED

TRADE 
MARKS.

The Two Glenboig Brands are identical in quality and are used indiscriminately in the execution of orders.

GAS RETORTS HORIZONTAL, INCLINED, & VERTICAL RETORTS to New Standard Specification. Special Bricks and Blocks for all modern Gas Settings.

Telegraphic Address: "GLENBOIG, GLASGOW."

Glasgow Telephones No. 2120 Douglas, No. 3009 Douglas.

Coatbridge Telephone No. 25.

58 FIRST AWARDS

At International and Home Exhibitions, including Grand Prize at Brussels, 1910.

In every case the Highest Award given for Fire Clay Goods.

Contractors to His Majesty's Home and Indian Governments, and the principal National Arsenals of Europe. On the Admiralty and War Office Lists.

Works: GLENBOIG, GARTCOSH, and CUMBERNAULD.
Head Offices: 48, WEST REGENT STREET, GLASGOW.

DEVELOPMENTS IN GAS CALORIMETRY.

By Prof. C. V. BOYS, F.R.S.

Mr. C. F. Botley (Vice-President) took the chair in the absence of the President—who was detained at the luncheon—and called upon Prof. Boys to give his paper. (The President arrived later.)

Introductory.

Members of this Institution may remember that on a former occasion I gave an account of the progress which I had made in constructing a recording calorimeter; in fact, I showed this in action at the meeting. Subsequently I lectured on the same subject at the Royal Institution, and showed in action the instrument which I had constructed myself, and also one constructed by Messrs. John J. Griffin & Sons, Ltd. I showed also a "spot-test" calorimeter and meter, based on those of the recording instrument, and I indicated that this spot-test instrument promised advantages, especially in testing the gas of the smaller undertakings.

It was immediately after this that I first came in contact with that very remarkable material "onazote," or nitrogen-filled rubber, which is the most perfect non-conductor of heat known at the present time. The possibility of using this not only as non-conductor but also as water-containing material made into any form by the direct process of moulding, and so avoiding altogether the use of metal for this purpose, indicated such manifest advantages that, whether wisely or not, I determined that such advantages must be attained. I did not realize how long it would take to get a start on experimental construction. However, when the first "Block" calorimeters were made after inevitable difficulties had been overcome, their behaviour was so admirable that I felt the delay had been justified by the event. The Gas Referees had these under observation in their laboratory, and were satisfied; and then trials conducted in official testing places confirmed the accuracy and convenience of the new instrument. They found after a further lapse of time, however, that these instruments were beginning to give results which at first were almost imperceptibly in error, and which after a time showed increasing irregularity. After repeated attempts to cure this trouble had proved unavailing, I was driven after a loss of two years to abandon the use of onazote as a water-containing and insulating material, both for the recording and the spot-test instruments. If the inventor should succeed in overcoming the difficulty due to contact with water, its use might be considered again, but after this experience it would require the test of a year's service at least.

With disappointment and regret, therefore, I have had to go back to the form of calorimeter which I showed at the Royal Institution, and which it is convenient to distinguish as the "Box" calorimeter, and it is upon this and the consequent equipment suitable for small country places that I wish to speak more particularly to-day.

The Box Calorimeter.

In carrying out their duties, the Gas Referees have been much oppressed by the cost and elaborate procedure which have grown up round the ordinary water-flow calorimeters, and which make their provision a burden which is serious in the case of small country places. This applies less to the equipment within the testing place than to the time required of the Gas Examiner and the tedious nature of the operation which he has to conduct.

It is with a view to reducing this burden that I have designed the complete equipment illustrated in fig. 1. In this it will be seen that the water required for the test is contained in a small tank standing on a stool on a table, and that the water, after passing through the calorimeter, is received in a similar tank below the table. For this reason it is unnecessary that water should be laid on or that a sink or drain should be provided, and the table may be made to stand in any convenient place to which the appropriate gas supply can be taken. The use of the same water over and over again, whether this water is distilled water, clean rain water, "tap" water, or boiled tap water, has certain advantages. While the gas in different places may differ, no trouble to the calorimeter arises on that account. On the other hand, the local water may differ, and the possible action of extra hard water on the one hand or peaty water on the other has been an anxiety rather than a material inconvenience. However, only recently the Gas Referees have met with a case where trouble has been caused by the fact that the water from the street mains appears to be a kind of soda water, and evolves so much gas as to interfere with continuous running of the present instrument, and to necessitate special measures. The re-use of the water not only removes the difficulties due to its doubtful quality, it also has the effect of causing the water to be very closely the same in temperature as the room in which it remains and the air used for combustion. A gas burner is provided below the upper tank, so that the water if too cold may be warmed.

Two other features of the water circulation are worthy of note. A hand pump is provided on the right-hand side of the table so that the water may be pumped back to the upper tank. The delivery pipe leads this water to the bottom of the tank, so that, by continuing the pumping operation, air is pumped into the water, and the stream of bubbles causes circulation of the water and uniformity of temperature. I have done away with the overflow funnel system for determining the water rate, and replaced it by a carburetter device derived from motor-car practice. When the main tap of the upper tank is turned on, the water runs into a down tube, with the usual perforated disc at the lower end. When, however, the water has reached a certain level, a float carrying a needle valve arrests the flow of entering water until it is just equal to that leaving the orifice below, so that the water is maintained at a constant head, and a constant flow is assured. The down tube can be moved to a back-stop, and then the water merely runs into the lower tank, or to a fore-stop, in which case it passes through the calorimeter. The water which has passed through the calorimeter leaves by a swivel outlet tube moving between stops. At one position of the tube it runs away to the lower tank, while at the other it is directed into a measuring flask like an ordinary litre flask, but with a divided neck, so that the amount run out while the meter drum makes (*e.g.*) four or five complete turns may be determined with great accuracy.

The water circulation within the instrument is very similar to that already described in my recording instrument, except that there are no operative thermometers, and the inlet and outlet thermometer ways are only $\frac{3}{4}$ in. in diameter. As in my recording instrument, the hot water leaving the hot thermometer tube passes through a helix of copper pipe round a cylindrical copper shield surrounding the calorimeter structure down to that level at which the water rising in the lead interchanger begins to change in temperature rapidly. By this means the insulation round the hot part of the instrument is relieved of the duty of preventing loss of heat to the casing which may be 10° or 20° C. cooler than itself, for it is surrounded by a shield of sensibly the same temperature. The insulating material which I have finally selected is compressed cork, such as is used for cold-storage insulation, round the interchanger, and granulated cork filling the wooden casing, well packed in and protected from access of moisture by means of an ebonite cover hermetically connected to the upper ends of the water passages in which the thermometers are placed.

Turning now to the gas circuit, the gas to be tested is brought from the service pipe to an efficient governor such as two governors in series, thence to a T, where one portion of gas passes away to a clearing burner, so that live gas may be tested, and not that only which is dormant in the service pipe. The other branch of the T leads through a micrometer tap to the Boys Bell Meter, and so to the burner. This consists of a narrow inner tube terminating within a plain parallel silica tube open above and below, which latter is held in a spring clip, and so can be moved down to be lighted and then be pushed up to its

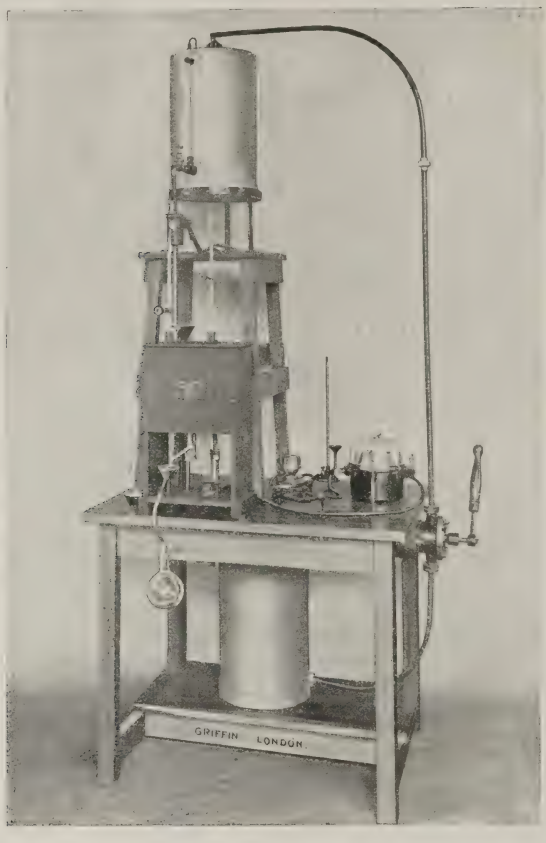

FIG. 1.

upper limit. This burner has the advantage that no moving gas connections are needed, and that the gas is somewhat aerated before combustion. It is, therefore, possible to burn as much as 1 c.ft. per hour without the formation of smoke or risk of imperfect combustion. The hot gases rise up to a silica dome and descend within the lead interchanger as in the recording instrument already described, and then entering an annular lead bowl are led down through the table, together with condensed water, by means of a lead duct. It is merely necessary for the Gas Examiner to find the position of the micrometer tap that will allow of the intended number of complete turns of the meter drum while the water is filling the flask up to some point in the neck, and this setting may be repeated with such small variation as may be convenient from day to day. As the exit water acquires its final temperature in a quarter of an hour, and the Gas Examiner has to make no adjustments of gas (after the first) or of water, and as, moreover, the tiresome process of proving the meter is unnecessary, it will be seen that the work of the Gas Examiner is curtailed and simplified.

I have so far described the Box calorimeter and its equipment merely as a calorimeter. The equipment, however, makes it possible for the table to be in itself a complete testing place. Then instead of a stool to carry the upper tank, a cupboard would be used in which the Gas Examiner could lock up all his books and papers. On the side of the cupboard there is room to fix the pressure gauge and the sulphuretted hydrogen apparatus, and a hinged flap in front would provide a convenient writing slope.

The Boys Bell Meter.

I have referred to the Boys Bell Meter, but a few words on this may be desirable. The ordinary test meter delivering one-twelfth of a cubic foot per revolution when in good order is a perfectly good instrument, but the Gas Referees have had much trouble in testing places, chiefly from "sticky" meters, that is those where from imperfect lubrication or other cause the friction in the stuffing box is both great and variable. They have also been troubled by small leakages developing in a surprising number of points of the meter, and also in badly made stoppered T's of the meter-proving measure. I have, therefore, wished to find some way of getting rid permanently of all these faults. When designing the recording calorimeter, the meter problem was forced upon me, and I believe the whole of these troubles have disappeared for ever in the meter I then designed. The chief peculiarity of the recorder meter was the use of a drum loose upon a screwed axle. The axle was turned at the required rate by clockwork, and the drum, relieved of all axle friction, was turned by the incoming gas. If the gas entered too fast, the drum turned faster than the axle, screwed itself along, and by so doing reduced the gas supply. The drum had no work to do except that of turning in the water, and thus the irregularity of gas flow consequent upon variations in gas pressure or friction were wholly eliminated. I am unable to use this feature in the Bell Meter as adopted for independent use, but I do retain the advantages of the original meter; for there is no stuffing box, but the axle moves in bearings in the water of the meter. (Fig. 2.) I still retain the buoyancy chamber which supports much of the weight of the drum, and besides forms a solid floor to the major part of each compartment at the critical moment at which a charge of gas is trapped within it. Leakage is impossible, as the drum is covered with a glass bell, making a joint with the bowl below the water level, and this allows the drum itself to be seen and its smooth working observed. Finally the water level is determined by the use of a submerged needle, which just disturbs or does not quite reach the surface of the water during the work-

Fig. 2.

ing of the meter. This level can be ascertained by reflection from the surface with far greater accuracy than any water line on a window can be read, and the actual level is made of less importance by the existence of the buoyancy chamber. In fact, this is its primary object. For these reasons this meter has great advantages both in accuracy, convenience, and, I believe, permanence over the usual form of meter. Provision is made for adding or subtracting water when setting the water level by the point, and the elimination of the operation of meter proving is itself an advantage. I used celluloid as the material with which to construct the drum, and its transparency is certainly an attraction. Messrs. Griffin are making the drums either of celluloid or of pure nickel. The capacity of the drum for the recorder and spot-test instrument is $\frac{1}{10}$th c.ft.

It would be almost too much to expect that where so much is gained from a radical change in design there should be no new fault or inconvenience. I know of only one inconvenience. Where the bell meter is left in a room which falls in temperature, especially if it is just below a window, the glass cools more than the water, and condensation occurs which in time completely obscures the view and makes observation impossible. This is best kept down as far as possible by covering the whole meter when not in use with a large protecting case. Any dew which may nevertheless be formed can be removed either by the application of a warm rubber water bottle made to fit over the bell, or simply by radiation from a luminous flame. If by either of these means the glass is warmed even a very few degrees, the water upon it will rapidly evaporate and condense on the water again. I have not yet been able to prevent the formation of dew by any coating within the glass, and I have not as yet cared to try the use of salts solutions with a smaller vapour tension, but that is a possible cure.

In a few cases where inconvenience had arisen from the necessity for frequently proving the usual meters and from other causes, a Bell Meter of $\frac{1}{15}$th c.ft. capacity has been substituted, and those in charge have approved the change.

Average Calorific Value of Gas.

Still confining my observations on this occasion to the needs and difficulties met with in the case of small undertakings, there is one for which up to the present the Gas Referees have not found a solution which can be considered altogether satisfactory. The difficulty is to find a value for the average calorific value of the gas supplied, when financial considerations unduly limit the number of tests. If the number of tests is too small, obviously there is a risk that the gas from a small works, of necessity more variable in quality than that to which most of us are accustomed, may be on the very few occasions of test caught at an unhappy moment when it is in a state of depression. Tests made at such times and unbalanced by tests made at more favourable times may give an unfair value for the average that has been actually delivered, and it is very little consolation to the Gas Manager to know that in the course of years the value must average out all right, if his undertaking is discredited on the unhappy occasions, and gets no credit for those in which he excels. It is not possible to remedy this hardship by increasing the number of tests indefinitely or even at all, because the cost of the tests becomes an item in the local rates, and the local authorities might refuse to make any test at all. As it is, it is only too often found that the limited number is considered excessive by the local authority. The result is that the number finally determined is a compromise, and like all compromises is not altogether satisfactory to any of the parties. The consequence is that the small gasworks have to provide gas which on the whole is of better value than that which they have declared if they wish to be safe from an adverse report.

It is to reduce this hardship that I have brought forward the simplified testing appliances and method described above. But that is not all. I now wish to indicate a further possibility—it is not more than that—that of obtaining a fair average value by a method of sampling, but here I am treading on delicate ground. Gas engineers know from experience that gas kept in their holders does not always retain its full value, and any system of testing gas that has been kept any length of time will be looked at with the gravest suspicion. All I now do is to ask you to remember that gas stored in holders and exposed to the cold at night may well have condensed out of it volatile and valuable constituents, and that such gas especially in cold weather may fall off in value. What I am now suggesting as a possibility is that in small country places the gas should be slowly and continuously drawn into a small holder in the testing place which is not exposed to the cold of the night sky, and that the Gas Examiner should make a test on the gas which, if there be no loss of quality, is an average of all that has been delivered since his last test. I am not saying that there is no loss of quality. I do not know, and in these matters it is unsound to assert that there can be no loss of quality because we do not know why there should be. That is a matter which can only be ascertained by direct experiment, and with all the different kinds of gas provided in the country it does not follow that the answer will be the same for all. Fortunately the gas engineers and gas chemists throughout the country are able to examine this question, and, in fact, without their help it would be impossible for the Gas Referees to examine every make of gas. With this explanation of the position, and remembering that what I am now putting forward is no more than a possibility which the Gas Referees could adopt only if found satisfactory and not otherwise, I think it desirable to explain the suggestion in more detail, and its many advantages to every interest concerned.

The sample of gas would be collected in a special gasholder in the testing place, maintained if necessary at a uniform temperature. The gas from the service pipe would pass through a governor to a T where one branch would lead to a clearing burner, while the other would lead to the holder. The governor would reduce the pressure to a fraction above atmospheric. The gas would enter the balanced bell and lift it as fast as a clock over the bell would allow. The chain from the bell to a balance weight made as a sprocket chain would pass over a sprocket wheel connected by a clutch to a clock-turned axle, the clutch acting in such a direction that the bell could not rise faster than the clock allowed, whereas it is always free to descend when weighted. The clock would be so geared that the bell would fill in any preordained time. In the example on which I have extemporized such a contrivance the bell fills in a week, but the time may be varied indefinitely. When a test is to be made, the incoming gas is cut off; the gas in the bell is led to the burner of the calorimeter, and the continued going of the clock has no influence on the outflow. The bell may then be weighted as desired. As a complete test may be made with the Box calorimeter in 25 minutes, and the gas is burned at 1 c.ft. or less per hour, a holder of very moderate dimensions only is needed. In the bell now before you, which was made by Messrs. Griffin & Sons, the annular space between the bell and the dumpling is as narrow as is consistent with free working, and the dumpling is above the water level. In consequence the gas is in contact with a very narrow ring of water only, the object being to make diffusion of soluble constituents of the gas as small as possible, so that when once the water has become saturated there should be no appreciable loss from this cause. The bell should not be filled so much as to leave less than say 2 in. of its edge immersed.

In taking the sample the question arises, what is the fair thing to do at night, say, for six hours, when the amount of gas passing in the mains is so very small. It does not seem fair to the gas undertaking to sample this equally with that passing in the busy hours of the day. One advantage of the clock sampling is that it lends itself to any system which in the future might be determined. For instance, a rough-and-ready plan would be to let the clock cause a detent to engage with the chain, say from midnight to 6 a.m., and stop taking in any gas at all for that period. Or, if it is considered better to take some account of night gas, the detent would be replaced by a slower moving tooth engaging with the sprocket chain or chain wheel, and the bell would take in gas at any reduced rate that might be desired. It is not necessary to show how any variation of rate could be produced. The mechanism is so simple that any proposition can be met.

There is one detail about the bell holder that should be mentioned, and that is the use of a sprocket chain of such weight that 1 in. of it weighs as much as $\frac{1}{16}$-in. length of the sides of the bell. Or, if that is too heavy to be convenient for the chain, then an additional idle chain passing over a pulley should make up this weight. By this means the change in the pressure of the gas caused by changing immersion and buoyancy is eliminated, and a governor between the bell and the burner becomes unnecessary.

Having now indicated, I hope sufficiently clearly, my proposal for obtaining a fair sample of the gas, I would ask you who have the control of small country works to consider it for the present as a kind of fairy tale which, if time and experiment should prove it to be true, should appeal to you as the work of a kind fairy. While you are doing your best with the manifest disadvantages which surround the manufacture of gas on a small scale, and while you are supplying gas which taken all round is all that you are required to supply, you are relieved from the unfortunate effect on your average of a test made at an unhappy moment, but are given credit for what you have done. And if any should be here who represent the consumer, and after all we are all consumers, then you equally are assured that a satisfactory test means that you have got what you have paid for, at least as far as the average goes. If it should all work out well, the more important object of the Gas Regulation Act would be attained, and this for the smallest place and at the minimum of cost. The consumer pays for value received and not merely for cubic feet of nebulous material. This test does not meet that other requirement of the Act—the 6 p.ct. two hours' minimum. This can be looked for as at present by a gas examiner whenever he tests, for he can examine the current gas as well as the stored gas.

Discussion.

The President: I think we are to be congratulated as an Institution in having as Gas Referees men like Prof. Boys, gentlemen of high scientific attainments who are not satisfied merely to administer the Gas Regulation Act, but who do all they can to help us to see that the gas we supply receives its full value. In Prof. Boys we have not only a scientist, but a gentleman of high mechanical attainments; and I desire to offer him on your behalf, not for his paper, because I do not regard it as a paper, but as a wonderful lecture, our very best thanks. When I asked Prof. Boys whether he would be good enough to give us a paper on gas calorimetry, he immediately said he would be pleased. Unfortunately, Prof. Boys, like myself, is not a young man, and he has not been very well; but we rejoice to see that he is able to come here this afternoon and give us this wonderful lecture. What we as an Institution and as the gas industry desire is that our gas shall be registered accurately, and Prof. Boys, by his invention, has been able to devise an instrument that can be placed in the hands of those in charge of the smaller works, so that they can see that the gas which they supply is of full value. This, of course, is most important for the smaller undertakings. The larger works can afford to have skilled chemists; but that is impossible in the case of the smaller works. And I am sure it will be to the benefit of the gas industry if we can place at the different works a recording calorimeter which will give us the exact value of the gas that is being supplied; and we want no more. My connection with the Gas Referees has been a most happy one. I find that they are not antagonistic to us; and while they carry out, as they are in duty bound, the regulations of the Gas Regulation Act, they are very anxious to assist us. By your large attendance this afternoon you indicate the interest you take; and I think it is a compliment to our friend the Professor that, notwithstanding the beautiful weather, you have turned up in such large numbers this afternoon. I, as your President, tender to Prof. Boys our grateful thanks not only for his lecture this afternoon, but for what he has done to help us in the measurement of the calorific value of our gas. [Loud applause.] Gas is now sold on the heat basis instead of on a volume basis; and, as one who has supported this from the first, I am very glad to know that most of the gas companies in the country are now selling their gas on this basis, because we know the value of gas lies in its heat value, and therefore it is most important, in view of the enactments with reference to the quality of gas, that we should receive full credit for the quality that we send out. I am therefore delighted to know that we are now likely to have a recording calorimeter that we can, with the utmost confidence, place in large works and small works, and know that the register we get is the accurate value as sent out during the whole 24 hours. If anyone would like to ask Prof. Boys any questions, I am certain he will be very pleased to answer them.

Mr. R. S. Whipple (Cambridge Instrument Company): May I congratulate Prof. Boys on the beautiful invention he has brought before us? I feel that it is characterized, as all Prof. Boys' inventions are, by its absolute simplicity. He has dwelt a little bit on the difficulties of making a calorimeter; and if I may be allowed to say so, I, in a very much humbler sphere, know something also of the difficulties of evolving a satisfactory calorimeter. My colleagues and I at the Cambridge Scientific Instrument Company have been working for some time on a calorimeter, as Prof. Boys knows; and the time that passes away in some intangible manner in the experimental work does impress one very much indeed. You have to go on for a very long time before you can say that a particular calorimeter or a particular modification is a success. This, of course, is not only the experience of men making calorimeters, but it applies in many other directions also. I understand that in the case of Rolls-Royce cars, Mr. Royce has given definite instructions that no improvement or modification of any kind can be adopted on a car unless that improvement or modification has been tried for 10,000 miles on a car, and it is actually a fact that there are two or three Rolls-Royce cars running all the time in France trying-out improvements, because there are speed limits and police difficulties here which do not exist in France. This shows that even in engineering problems of that kind a great deal of time slips away. Prof. Boys has passed briefly over some of his difficulties; but I do not know whether it impressed you, as it did me, the way he has got over the radiation difficulty in the box calorimeter. I suppose he has used the analogy of the cascade electric furnace, where you heat outside in order that you may prevent radiation from the heat inside. I should like to ask whether he has thought at all of using kieselguhr as a heat-insulating material—that rather wonderful material which consists of some form of shell-fish or microscopic sea-shells, and which has the advantage that you have a large number of air spaces between the little pieces of shell, and I also think it is pretty independent of moisture. You can wet it without introducing very serious errors. Then, with regard to the gasometer, I think it is rather surprising that that has not been thought of before. For sampling the calorific value of coal, you take a little out of your various trucks, and lump them all together, and take a mean calorific value of the different samples; and it is really extraordinary that no one has thought of this extremely simple, yet very beautiful, invention of Prof. Boys, of having a gasometer which you simply fill up at a definite rate. I have no doubt that before long Prof. Boys will immerse the whole gasometer in a thermostatically-controlled water bath; and if he does so, I imagine that the difficulties of condensation and the other troubles he mentioned will practically disappear. I wonder if I might be allowed to tell you something which Prof. Boys has not mentioned, and that is that during the past twelve months he has received medals from two Societies for the invention of some of his instruments—viz., the Rumford Medal of the Royal Society, and the Duddell Medal from the Physical Society.

Prof. Cobb: I do not know that I have anything to say concerning this address by Prof. Boys in any spirit excepting one of unqualified admiration and eulogy. It is always a great pleasure to hear a gifted experimentalist tell the story of his own experiment, an inventor to tell the story of how his invention has gradually evolved; and this, I think, is probably the main source of interest in what Prof. Boys has had to say this afternoon. When the Gas Regulation Act—or, rather, the original recommendations on which the Gas Regulation Act was based—was made by Sir George Beilby, I think that a number of us thought that this question of how the quality of gas for primary purposes was to receive continuous record had been treated rather lightly; but that it is an extremely complicated question you will have been able to gather from the examples which have been put before you so lucidly by Prof. Boys this afternoon, without indicating the high degree of complication which is really present in some of the questions which have received a comparatively simple solution under his expert treatment. As I say, they are really very complicated questions demanding the attention of a skilled and thoughtful

experimental physicist, and Prof. Boys is to be congratulated on his labours in that connection, and the gas industry is to be at least equally congratulated.

Dr. H. G. COLMAN: I have been exceedingly interested in this matter, and will just refer to one point on which Prof. Boys asked for information—not that I am able to give him any information beyond what he has said. Regarding the variation of the gas when stored in a holder of this sort, he said he thought no chemist would give a definite answer, though he himself did not see any reason why there should be be any loss until he had made further experiments. Some years ago I did make some experiments, but I am not yet able to say anything much more definite than Prof. Boys has said. When gas was stored in an arrangement such as Prof. Boys has here, in which the temperature is maintained reasonably constant, I was never able to find that there was any definite loss, to a greater extent, at any rate, than 1 p.ct. At the same time, the number of tests I made were quite insufficient to make it a definite proof; and further investigation under varying conditions of gas is required, and would be of very great value to the industry, and certainly to the small undertakings, though perhaps, also, to others; but it can only be done by a large number of people undertaking the work.

Mr. J. W. WOOD: It has been my good fortune, on behalf of the Institution of Gas Engineers, carefully to examine three calorimeters which have been proposed for use; and so far as one can see, all the instruments proposed had certain defects, but there seemed a reasonable chance of any one of them working, at any rate to a practical extent. I was rather unfortunate in not being present this afternoon during the whole of the meeting, and listening to Prof. Boys' remarks. As Prof. Cobb has said, it is extremely interesting to listen to the remarks of a man who has carried out the experiments himself, and knows what the difficulties are, not merely of devising a principle, but in carrying his apparatus to such an extent that he can obtain quantitative results within comparatively close limits. The apparatus we have seen to-day compels admiration in every respect. Naturally, in my position in examining calorimeters, I am rather interested in technical details, but there is only one small point on which I should like to ask Prof. Boys a question, and that is what provision has he with his gasholder for blowing-up the holder. Is there provision to keep the rate down if the pressure on the supply system goes up unduly; and what provision is made if for any reason the gas supply should fail? Dr. Colman made some remarks about the variation. As long as we are concerned with permanent gases or comparatively volatile vapours, I see no reason why we should expect any variation of gas in a holder of this kind, provided the bell is constructed of suitable material. On the other hand, there is just the possibility that, in certain circumstances, on the cooling of the bell, compounds will be thrown out which, either by polymerization or for any other reason, remain permanently there, and then dissolve the other constituents of the gas, leading to a permanent deterioration of the gas in the bell.

Dr. E. W. SMITH: I should be glad to know, if the calorimeter is to be available for small works—I expect it will be—and will enable the engineer to carry out tests accurately in a very short time, why it should not also be valuable to large works. Prof. Boys assumes that a large works has chemists; but these chemists are highly paid—or should be—and their time is valuable, and some of them could either be dispensed with to some extent, or they could be put on to more valuable work. Therefore, I should like Prof. Boys to tell us why he does not suggest that this instrument would be useful on large works as well as small. I have been wondering whether the engineers of small works who are not going to carry-out regular tests to check up the long sample will be prepared to wait until the end of the month or week to see what their test would be, or whether they should carry-out fraction tests, and correct them for what they now call a bad average, and put the matter right. As regards the use of the holder, Mr. Whipple perhaps does not know that in Birmingham and many other works it has been the custom for many years to sample the make of gas continuously like that in 100 or 200 c.ft. holders, but not by clockwork means. If Prof. Boys can tell us whether it is proposed to sample the gas that is sold, or the gas that is made, I should be glad. If the sample is to be taken on the make, that would be all right; but if the sample is to be taken on the gas as it leaves the works, then no amount of correction of speeds will account for the variations in output, apart from variations in quality and in the demand from the consumers. I am delighted with the address, and should like to congratulate Prof. Boys.

Dr. PARKER: There are a few points in this calorimeter on which I should like to make one or two observations. In connection with the sample holder, I understand that the lute which is sandwiched between the dumpling and the outer case is very narrow, and that this should cut down the solubility of the gases; but I should imagine that, if you take an average sample over a long period, you might alter the composition of the gas owing to solubility in the inner part of the channel, and the diffusion of gases, owing to a difference of partial pressure, into the surrounding atmosphere. I foresee some difficulty there. Whether it would go up or down in value, is rather difficult to say. Would it be too expensive in so narrow a channel to substitute mercury? It means having an iron gasholder instead of a tin one. Then, as regards the question of sampling in proportion to the rate of gas, Dr. Smith has raised the point whether it would be used for sampling the gas as made or as sent out to the district. In any case, perhaps, it would seem rather difficult to sample in strict accordance with a make which was fluctuating very considerably, unless the holder was geared to some main meter. In connection with some experimental work, we have the idea of sampling gas made at very different rates at different times, by gearing a small meter to the large main make meter. It may in some circumstances be possible to do this; but it depends upon Prof. Boys' idea as to where the instrument should be used.

Mr. T. F. E. RHEAD: I should like to ask Prof. Boys what will be the price of this instrument and whether it is possible to get it.

Mr. G. W. ANDERSON: Would the Gas Referees allow this apparatus to be used?

Prof. BOYS, replying to the discussion, said: I have at any rate this satisfaction, that I have had no bricks thrown at my head metaphorically on this very drastic suggestion that gas should be sampled continuously. I did not know how that revolutionary proposal would be received, but, as I have said, it is no more than in the air. Mr. Whipple asked about the use of kieselguhr. I know that material quite well, but I have not tried it; at the same time, I do not myself think that as a non-conductor of heat it is better than compressed cork. So far as the moisture question is concerned, speaking as I did this afternoon, and depending upon the exuberance of my own verbosity, I naturally forgot to say many things that I intended to say. One of them was that the whole of the cork insulation inside the box type is absolutely removed from all possible contact with water. You might spill water on the calorimeter, but none would ever get anywhere near the cork. Thus the question of the cork being made damp does not arise. And, after all, if kieselguhr is made damp, I do not think it would insulate heat as well as if it were dry. Again, I forgot to say, in connection with this gasometer, that there is a sprocket chain which goes round a sprocket wheel. This wheel is not fastened to one of the clockwork wheels, but is connected by means of a clutch. I have used the same principle of a clutch which we had forty years ago in the old Cheylesmore tricycles, in which the wheel is free one way, but is instantaneously gripped the other way. In that case there were four rollers, one of which was always in a position to grip. I have made up something of the same kind here, and I have put in four $\frac{1}{16}$-in. steel balls, and one of them is always ready to grip, so that this bell can rise only so fast as the clock says it shall rise, and no faster. This answers the other question that was asked by Mr. Wood, as to the rate at which the bell rises with the gas fed into it from the holder through a governor. All this I forgot to say when I was speaking just now. Therefore, it is dealing with live gas, and not dead gas. This gas comes in at the pressure determined by the governor, and the clock determines the rate at which the bell rises. When the gas examiner comes along, and wants to test the gas, he pays no attention to anything else, but turns on the gas from the holder. The gas bell is weighted to $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$ in., or to anything you please; and when the gas examiner wants to test the gas, he does not interfere with the clock. The clock goes on ticking away, and this clutch device does not prevent the holder going down. The only thing the holder cannot do is to go up any faster than the clock says it shall; and it is the clutch arrangement which makes it so easy to adapt any device for altering the rate according to the scheme. I have said "according to the scheme," because I think that all methods of altering the rate according to the actual output from the works—and in large works you have several holders—is a hopeless proposition; and I think if, instead of having a hard and fast rule, we adopt some other rule which will fairly well meet the case, no one will be inclined to quarrel. We can say that from 6 to 12 in the morning we will take gas at a quarter the rate, or we can say we will not take it at all—that is a workable scheme. We can, of course, say that we will have all the gas-meters in the Gas Light and Coke Company's works connected-up with an epicyclic gear, so as to draw all their records together, and connect them electrically with all the testing places in London, but it is no use talking in that manner. It must be a workable scheme, and a practicable scheme, which fairly meets the case, and that is what I am suggesting now. You can, of course, suggest anything as complicated as you like. Dr. Smith has asked why this apparatus is not suitable for large works as well as small works. I do not remember saying it was not. I said I was addressing my remarks this afternoon specifically to the case of the small country works. As a matter of fact, I think it would be extremely useful in large works; and from what we have seen of this instrument at present I should very much prefer to use it instead of the standard Boys calorimeter, and use the whole equipment as you see it here. Though I did not say it, we

have been making very careful tests in the Gas Referees' Office. Our technical staff have been at work making a number of tests; and the results given by this apparatus and the Boys calorimeter are absolutely identical. There are slight variations from time to time, but on the whole the results are practically identical. I should very much prefer that the large works would use this instead of the old equipment. I think I have answered Dr. Smith's other question about sampling the gas leaving the works. Dr. Parker asked about mercury, and said this holder was made of tin; but it is not tin. It is either copper or brass tinned, and it is not what we usually call tin—viz., tinned steel. I have no use for things that do not last. Celluloid, as far as we know, is perennial; and this plated brass or copper holder is perennial in so far as it will not rust and break through. That, of course, would not be possible with mercury, and it would mean using steel or iron, which would be heavier. It would probably mean acetylene or oxy-acetylene gas welding, which now has become quite an easy operation. It could be done, but there would be a little expense in the mercury; and I do not know whether it is worth while. I did not catch the name of the gentleman who spoke about the soluble constituents in the water, and the division of these constituents down in the bell and up again, and evaporation into the air; but it was evidently put by a chemist of experience. If you give it long enough, this will take place; but at what rate it will occur with any gas I do not know. We have not got to the length of giving this a three months' test; but it may be of interest to you if I mention another thing which I also forgot—that the only gas which we have been able to test, the Gas Light and Coke Company's gas, in Victoria Street, has shown no change at all after a fortnight's test. I had hoped, when I got this holder last year, to have had, by this time, particulars of many tests of longer and shorter duration. We started with the old box calorimeter with onazote, but we could not use it with the Boys calorimeter, because it does not hold enough gas. Moreover, the accuracy of the tests when using onazote with the box calorimeter were not reliable, because onazote was found to be not perennial, and it is only recently that we have got the instrument that you see on the table. There was one other question, as to whether the instrument can be obtained. I must refer you to the makers as regards this. I am certain that the people who make these things do not make them for fun. I believe they want to sell them, but I have nothing to do with that part of the business.

The President: I will now ask you to accord Prof. Boys a hearty vote of thanks for his lecture, and can only express the hope that this calorimeter will be evolved soon in a form in which it can be used practically.

Prof. Boys: I must thank you for receiving this paper in so favourable a manner. I may say that I began to have awful misgivings towards the end of last year, when, after the lapse of six solid months, I wondered what I was going to do, because the onazote on which I had built all my hopes was gradually fading away. I did not know what would be the end of it, and so the time had to come when I had to do something. So I cut adrift my ships and went back to where I was two years ago; and here we are. [Loud applause.]

The President: With reference to the Rumford Medal of the Royal Society which has been presented to Prof. Boys, I, as your President, when I saw the announcement of that award, wrote to Prof. Boys and congratulated him. I am sure this action will be endorsed by all present. [Applause.]

A Furnace Repair Gun.

For the purpose of re-lining, patching, or surfacing furnace walls with great speed and at low cost, the "Quigley Refractory Gun" is being marketed by the Quigley Furnace Specialties Company, of No. 26, Cortlandt Street, New York. It is operated by compressed air, and with it refractory materials of plastic consistency can readily be applied to places not easily reached by hand-patching methods. Pre-mixed refractory material is placed in the gun. The nozzle is then pointed at the place to be repaired, and the gun operator, by handling the valve controls, forces the mixture from the gun through a section of hose to the nozzle, where the repair man makes the application. The pressure required will vary from 50 to 100 lbs., according to the nature of the material. The gun consists of a cast-iron cylinder, from which the material is forced by pressure applied to the piston. The gun has a capacity of 2 c.ft. of mixed material, and is mounted on wheels, so as to be easily movable from place to place.

Gas Oil.—The "Petroleum Times" reports that, dating from the 3rd inst., the price of gas oil is reduced by ¼d. per gallon to 5¾d., net and naked, *ex*-wharf.

Canadian Gas Association Convention.—A highly instructive and interesting programme of papers is announced by Mr. G. W. Allen (the Secretary-Treasurer) for the forthcoming annual convention of the Canadian Gas Association. This will take place in Quebec City, on July 15 and 16. The papers number 11 in all; and one of them is to deal with the subject of "Heating Vertical Retorts with Coal Gas."

NOTE ON TOWN GAS FOR MOTIVE POWER.

By SIR DUGALD CLERK, K.B.E., D.Sc, F.R.S.

Past President and Hon. Member of the Institution of Gas Engineers.

Town gas is by far the best fuel which has yet been produced for use in internal combustion engines. It is clean, it is uniform in its composition for each district, and its continued supply can be depended on; engines driven by it require a minimum of attendance and lubrication. Internal combustion engines of from 2 H.P. to 1000 H.P have used it successfully for many years. At present about 10 p.ct. of all the town gas manufactured and distributed in Great Britain and Ireland is used to produce motive power. The total power is approximately 360,000 brake horse, or about one-half of all the stationary internal combustion engines at work in our factories. The thermal efficiencies obtained are high; they vary from 25 to 30 p.ct. in the standard types of gas engines built by first-class makers. They are readily started, and can be relied on for long periods of service without breakdown of any kind. This is recognized by the small premiums required by the leading engine insurance companies.

Before the war the power of town-gas engines in use in all countries expanded rapidly. The war disturbed the trade, but now the industry is steadily recovering with the general slow recovery of the engineering and manufacturing industries of the world. The losses of war have, of course, impoverished all nations on this side of the Atlantic, so that our former customers abroad have too little money available to enable them to make their usual purchases from us. It is to our interest to trade with prosperous, not "poverty-stricken," nations, and we cannot expect to recover fully without the commercial recovery of other nations. It is our interest to help the recovery of our former rivals because they were also our former customers.

With the recovery of our overseas trade will follow that of our internal trade, and then the use of town gas for motive power will continue its war-interrupted increase. At present the balance of forces has been altered, and engineers are aiding recovery by the most rigid economy and economization of all available means of reducing the cost of motive power. Before the development of electricity, town gas enabled gas-engine builders to displace steam power up to about 100 B.H.P. At this power the lower price of heat evolved from coal burned directly in the boiler furnace balanced the higher-priced heat from gas notwithstanding the much higher thermal efficiency of the town-gas engine.

The pre-war cost of heat obtained from town gas varied from 2d. to 4d. per therm, while the heat direct from suitable coal was about 1d. per therm. The thermal efficiency of a small steam engine was never more than 5 p.ct., and that of a town gas engine never less than 20 p.ct., so that coal in a steam boiler would produce the same power from four therms which the internal combustion would produce from one. At about 100 B.H.P. a good steam engine will give about 8 p.ct. thermal efficiency, so that the fuel cost per B.H.P. falls below that of the gas engine. There is obviously a point when the fuel cost of gas for power exceeds that of steam due to the relatively rapid rise of efficiency with increase of steam-engine dimensions.

The gas-engine efficiency remains practically constant from 5 to 100 B.H.P., and this enables the smaller engines to work more economically than steam engines of similar power. Accordingly it is found that the great majority of town-gas engines at present in use are below the 100 H.P. limit. It is true that gas engines are run on town gas at powers of 150, 300, 450, and 1000 B.H.P. with complete engineering success, but the fuel cost is too great at the usual selling price of town gas to lead to general use in cities.

Many large engines are run on coke-oven gas for generating electricity for use at the pits, and many are used with blast-furnace gas which was formerly wasted or used most inefficiently under steam boilers.

Internal combustion engine builders are deeply indebted to the town-gas industry for the rapid development and success of their engines; they feel, as I have said, that no better fuel could be produced than good coal gas, and if it could be supplied at a sufficiently low cost per therm gas engines of every power would adopt it. At present, however, the price of 4d. to 6d. per therm is too high to compete with other sources of power above 100 B.H.P.

In order to develop a large engine trade it was necessary for engineers to attend to other means of obtaining motive power gas. This led to the invention and rise of the pressure and suction gas producer. In the suction form good anthracite and coke is completely converted into producer gas of from 130 to 160 B.Th.U. per c.ft. with a thermal efficiency of about 85 p.ct. The producer gas is admirably efficient in both large and small gas engines, and accordingly many thousands of horse power have been successfully operated within my personal experience at a cost for fuel less than that of coal gas. The producer, of course, adds to the cost of the power installation, and the attendance required costs more than that of a town-gas engine, but the total cost per H.P. hour is reduced.

Comparison of Cost by Town Gas and Suction Producer with Anthracite for 50 B.H.P. at 50 Hours Week.

Town gas at 2s. 6d. per 1000 c ft. and 475 B.Th.U. net value, or 6·3d. per therm. Heat consumption per B.H.P. hour = 0·0975 therm.

Cost of Gas per Week.	Interest and Depreciation on £350 at 10 P.Ct. per Annum.	Water.	Lubricating Oil.	Labour.
£ s. d.	s. d.		s. d.	s. d.
6 8 0	13 5	*Nil*	5 0	10 0

Total cost per week, £7 16s. 5d.

Anthracite fuel (suction gas), 1 lb. of fuel per B.H.P. hour at 50s. per ton.

Cost of Anthracite per Week.	Interest and Depreciation on £370 at 10 P.Ct. per Annum.	Water, 2 Gallons per B.H.P. Hour at 6d per 1000 Gallons.	Lubricating Oil.	Labour.
£ s. d.	£ s. d.	s. d.	s. d.	£ s. d.
2 15 0	1 1 11	2 6	5 0	1 2 6

Total cost per week, £5 7s. 8d.

When coke is used at 35s. per ton and a consumption of 1·25 lbs. per B.H.P. hour, the cost for the week falls to £5 3s. 2d.

A modern heavy-oil engine of the cold starting type calculated out on the same basis of a week of 50 hours and 50 B.H.P. developed during that time requires £4 18s. per week.

Diesel crude oil is to be used, and its cost is taken at £5 15s. per ton.

The total capital cost is £530, and at 10 p.ct. per annum this amounts to £1 0s. 4d. per week; in this case lubricating oil cost 5s. and labour 15s.

The costs stand thus:

	£ s. d.	d.
Town gas	7 16 5,	or 0·75 per B.H.P. hour.
Anthracite suction gas	5 7 8,	,, 0·52 ,, ,, ,,
Coke	5 3 2,	,, 0·49 ,, ,, ,,
Diesel crude oil	4 18 0,	,, 0·47 ,, ,, ,,

In the four cases the fuel costs alone are town gas, 0·61d. per B.H.P. hour; anthracite suction gas, 0·26d.; coke suction gas, 0·23d.; and Diesel crude oil, 0·51d. per B.H.P. hour.

In the case of electricity supply for power, allowing a motor efficiency of 90 p.ct., the current necessary to produce 1 B.H.P for each hour would require to be sold at 1·125d. per B.O.T. unit without making any allowance for interest on cost of electric motor, oil, or attendance. Some companies sell current for motive power at and near this low price—for example, Ashton-under-Lyne and Sheffield. To meet this competition it appears necessary to do everything possible to reduce the cost for power town gas to 4d. per therm. The demand for engines run by town gas would thus increase, and the gas consumption for power load would rise again as

before the war. In those times a considerable number of towns had reached the low figure of 2d. per therm; such towns as Widnes and Sheffield are good examples.

With the gas of that time 1s. per 1000 c.ft. equalled 2d. per therm and 2s. per 1000; a very common price was 4d. per therm.

In Sheffield now gas for power costs 6·4d. per therm. I do not suggest that the cost of town gas for motive power is the only element accounting for the reduction in the rate of increase; bad trade is largely responsible, but the price of gaseous fuel forms a large factor in determining the type of motor to be used. I have been long conscious of this fact, and I pointed out the importance of cheap town gas for motive power to the Gas Institute as far back as the Southampton meeting of 1902, and in 1905. I read a paper on "Coal Gas and its Rivals for Motive Power" to the North of England Gas Managers' Association. In this paper I discussed steam engines, gas engines, and electric motors, and the relative costs, and I then said:

"Even at present prices, in most towns, gas motive power is very much cheaper than electrical motive power." I could quote cases which have occurred in connection with the business of the National Gas Engine Company when electricity at 2d. per unit has been replaced by them by gas, with the result that the cost of power was reduced to about one-sixth, and this with gas at 1s. 9d. per 1000 c.ft.

There is no doubt whatever that both electric lighting and electric power companies are pressing hard to supply motive power; and a certain field will doubtless always be theirs. For powers up to 5 or 6 horse, occasionally used, no doubt they will find a considerable field; but if equal pressure were applied by gas companies, in conjunction with gas-engine manufacturers, I am convinced that the electric lighting companies would be prevented from seriously invading the field of larger powers. Even the very small gas-power trade might be held against the electric companies if gas companies would combine to let out gas engines on hire in the same way as they so commonly deal with gas stoves. The electric companies adopt similar methods; and there seem to be no good reasons why the gas companies should not fix gas engines in the same way as the Tyneside Supply Company, in Newcastle, fixes motors—either on simple hire or else on the five years' purchase system.

I am glad to find that our distinguished President has started a system at Derby whereby the rate of installing gas engines is increased. I wish him every success.

I agree with him in feeling that the increase of the town-gas power load is very desirable both from the point of view of the gas companies and the general public. We are more fortunate now in the greater liberty allowed by law to the great gas industry to vary the methods of manufacture and the composition of the gas produced so as to combine in one gas supply a thoroughly good gas for producing light, heat, and motive power at a low rate per therm supplied. The increased use of town gas will prove a great boon to the whole of our population both domestic and industrial. It is, of course, important to the nation to study and develop the supply of light and heavy oil for motive power and heating. Both light and heavy oil engines have come into very large use for locomotion on land, on sea, and in the air, but when we consider that the total heat of the oil raised from the wells in the world is only about 4 p.ct. of the heat of the coal raised from the pits, it is quite evident that coal and its products, solid, liquid, and gaseous, still remain of the greatest importance to the present and the future of mankind.

Internal combustion engineers are fully alive to this, and accordingly they study and test every type of fuel found in the world, and have adapted most of them, including waste products, to the purpose of producing motive power by their engines. They have accordingly designed special types of internal combustion engines for various liquid fuels, such as petrol, paraffin, heavy oils, and alcohol, and for gaseous fuels derived from many sources, first of all and most important town gas, then gases of the producer type from anthracite, coke, bituminous coal, lignite, peat, wood chips, sawdust, cocoanut shells. Such woody materials are often available in other countries where coal or coal gas is not to be had.

I look forward with interest to the more extensive use of town gas for internal combustion engines in settled countries of our type, and to the further discovery of useful carbonaceous matter in the wilder countries which can be dealt with in producer-gas engines.

At the conclusion of the paper, Sir Dugald Clerk said: I see nothing in the world to prevent town gas engines being used in all sizes. It is simply a matter of cost. We gas engine designers and constructors would never have gone to the other gases had we not been forced to do so by the necessity of getting some fuel unit that was rather cheaper than the coal gas then available. If we could return to anything like the 2d. per therm of pre-war times, you would have an enormous increase in business. I do not suppose you can do it; but, if you cannot, you may get down somewhat. Some of the companies are down to 4d. a therm now, but 6d. a therm is too much. It depends on yourselves; and if you really feel that you ought to get the power load to increase your consumption, it can only be done by keeping the price fairly low.

Discussion.

The PRESIDENT: We are much indebted to our friend, Sir Dugald Clerk, for bringing the question of town gas for power purposes so well before us, and for giving us the actual facts. I am particularly glad that I was able to persuade Sir Dugald, who we know is extremely busy, to give us this paper, because no one in the country knows more about internal combustion engines than he; and we are much indebted to him, and to the gas engine builders, for the enormous steps forward that they have made of late years in connection with gas engines. I have taken a great deal of interest in the supply of gas for motive power purposes, and it has paid my Company very well. It is over 20 years ago since I decided to let out gas engines on 3, 5, or 7 years' hire-purchase. We fix them complete for a certain fixed sum per quarter. We have now gone a step further; and I am glad to know that it meets with the approval of such a distinguished engineer and scientist as Sir Dugald Clerk—there is no reason why gas engines should not be supplied on simple hire. It is very important that, if we are going to foster the supply of gas for motive power purposes, we should not only fix the gas engine, but take care to have that engine regularly inspected and indicated, so that we can guarantee to power users that they have only to telephone to the gas office, and immediately one of our experts will be on the spot to make any slight adjustments, so that they can rely on the gas engine working continuously, there being no danger of stoppage. I believe we have lost, in the past, a certain number of customers through gas engines, from various causes, breaking down, and there being delay in getting them put right. In these days, when manufacturers keep their factories going on full time for 50 hours a week, it is very necessary that they should be able to depend on the motive power they are using; and there is no reason why gas engines should not be installed, and why manufacturers should not be satisfied that there will no danger of any breakdown. I ascertained from the insurance companies the ratios of breakdowns with electric motors, gas engines, and steam engines; but as the returns are a few years old, I do not think it fair to quote them. The returns that I got, however, showed that the ratio of breakdowns with gas engines was less than with electric motors or steam engines. There is no doubt that in oil engines, and especially with the present low price of oil, and also in electric motors, we have keen competitors. There are certain places where the power required is small and intermittent, in which the electric motor is very suitable, but there are a very large number of cases, where the power is comparatively regular, where the engine would be running from 48 to 50 hours a week, and where the power is from 10 to 100 H.P., in which you could quite well substitute gas engines. But, as Sir Dugald Clerk has pointed out, it is essential that we keep our price for gas down as low as possible. We know that the electric supply companies have captured the power business through charging extremely low rates. They charge something like one-fourth of what they charge for lighting, and in some cases considerably less than that. I am not suggesting that you should go to these extremes, but I do suggest to you that it will be worth your while to make a cut as far as possible, and reduce the price of gas for power, to encourage the increase of the power load. There is, of course, no better load for a gas company than a power load running for 50 hours a week, winter and summer. I am certain that one of the results of this admirable paper this morning will be that the engineers of all gas-works will pay more attention to the subject of town gas for motive power. At Derby we have a clever skilled mechanic whom we obtained from one of the gas engine makers, and he visits factories regularly, and canvasses for power; and the results are most encouraging. I am afraid, with the small undertakings, it would not be possible for them to have a well-equipped power department, as the larger undertakings can; but as I suggested in my Address, I think it is a

case where the larger companies can co-operate, so that their power departments will be at the disposal of the smaller adjacent companies, and by that means we shall be able not only to benefit ourselves, but to benefit the manufacturers. At the present time trade in this country is in a deplorable condition, and one of the results is that manufacturers generally are being compelled to look at their costs. If you can convince them that they can reduce their costs for power purposes by the use of gas engines, they will be willing to consider the question. If you say to them, "We will put your engine down, and we do not ask you to pay anything except a small charge per quarter for hire or hire-purchase," then I am certain it will be an inducement in many cases to go in for gas for power. I do hope that the members of the Institution will see that we do not lose our power business without a struggle, and that it is our intention, if possible, largely to increase the use of gas for motive power.

Mr. GEORGE HELPS (Nuneaton): There is an old saying that "the best goods are wrapped up in a small compass," and here we have an example. I am in the happy position of being able to endorse every word that is in this paper. I see the great significance of it. I admire the wonderful mildness with which Sir Dugald Clerk bids us look to our methods. He has put the case before us much better than anyone with a bee in his bonnet, like myself [laughter], could; nevertheless, he gets home. He tells us what the costs of power are with gas at 6d. a therm, and there is a difference, you will see, between that and oil, of round about 50 p.ct. You will see for yourselves what that difference amounts to if you are selling gas at 1s. a therm, as most of us are doing. Sir Dugald Clerk tells us that, to compete with this power proposition, we should be selling gas at 4d. a therm. I myself, a short while ago, lost business because I could not sell at 3d., and I lost it to oil. He also shows us the effect of complete gasification, and shows us that the thermal efficiency of the producer to which he refers is 85 p.ct. That is very different indeed from what you read earlier in the week in a table where it was shown that complete gasification gave an efficiency of 69 p.ct. I am only sorry that Sir Dugald Clerk has not translated these figures into costs per ton of coal, but I am certain the only reason is because of his great consideration for your feelings. [Loud laughter.] He knows that he can bear me out that, if we take 1 ton of coal, we get 70 therms, or 700 B.H.P. The electricity people are getting 1000 B.H.P., and we can get it by complete gasification. Sir Dugald Clerk even refers to 2000 B.H.P. I am not going to bore you by discussing all these things, but these are the figures you have to look to. However, you do not want to listen to me further, and, as I said at the beginning, good things are wrapped up in small parcels, and sometimes quite useful remarks are uttered in a short time. I thank you for listening to me.

Mr. P. D. WALMSLEY (Great Yarmouth): There is one aspect of competition between electricity and gas which I am up against in my town, and that is that in some industries manufacturers must have electricity. They require it for the purpose of their businesses, (say) the weaving and textile industries—a small motor on each machine, which gives them a superior finished article. Therefore, I should like to have seen in this paper the cost of generating electricity by a gas engine, and afterwards supplying it to these small motors, and at what price we should have to sell town gas to compete in that way. There is another point in the paper which I think is lost sight of in a great many instances in competition between gas and electricity. The electricity people, in our case, supply as low as 1½d. per unit, whereas their actual generation costs alone at the generating station are 1·87d. per unit; and I would impress upon you the difficulties you are faced with when you are up against a proposition like that. The point is to ask their consumers what is the average price they pay, because many of them take electricity for lighting as well as power, and you will find that in many cases the charge for lighting is many times that for power. If you take the average costs to a consumer who takes electricity for lighting and power, I think you would find that in many instances it would pay the customer to put down a gas-engine electric generating set of his own. You should be able to convince many consumers that they can generate electricity by means of gas engines on their own premises cheaper than they can get it from a public electricity supply.

Mr. S. SHADBOLT (South Bank): The paper emphasizes perhaps better than many contributions we have had lately the absolute absurdity of the different methods of pricing gas and electricity; the absurdity being, of course, on the side of the electrical industry. The last speaker has given one instance, but coming, as I do, from the north-east coast, where we have super-power stations interlinked with systems of electrical distribution—which are, we venture to think, a great deal more to be feared than anything the Government is likely to promote—we find it is more acute still. In the general way, in active competition, we find that there is an unconscionable practice of absolutely fleecing the lighting consumer by the electric supply people, in order to under-cut the gas price to get power business. My own electrical competitor takes a bulk supply from one of the big north-east coast power companies; and not long ago a load came along in a pumping station for a water undertaking right outside my own gas-works. As a matter of fact, it was across the street, and the load was 100 B.H.P. for 8 hours a day. When the electrical people knew that I was after it, they went to the length of getting a special concession; and a special agreement was drawn up with their bulk supply people, which enabled them to cut the price to between 0·75d. and 0·9d. per unit. Yet the same people are charging 6d. per unit flat rate to all shopkeepers for lighting. We cannot compete with this, because I flatter myself that our industry has too much moral conscience, for one thing. On the other hand, one is sorry to have to admit that, though Sir Dugald Clerk rightly says it is a matter of cost when comparing forms of gas production—and cost alone, probably, for internal combustion engines—in electrical competition it is unfortunately with us a matter of cost and a good many other things when it comes to small loads, such as the convenience and adaptability of the individual drive. I am quite sure many like myself have found these to be more formidable points in competition than price.

Dr. E. W. SMITH: May I urge that gas engineers should not assume that the electrical industry is not moral because they adopt a system of the kind referred to by Mr. Shadbolt? I have been urging recently, and I do urge it at this meeting, that somebody, preferably the Institution of Gas Engineers, should start an inquiry in conjunction with accountants to consider what are the best commercial methods of selling gas. I am sure that a very good case can be put up for selling gas at 3d. or 4d. per therm at the present time by probably most gas undertakings. I am sure that it is absolutely uncommercial to sell gas for lighting at practically the same price as industrial gas, because domestic consumers are taking very small quantities, and there are high installation costs and so on. I do not need to go into that side of the thing at all, because it is one upon which we are all agreed; but there is no doubt that we shall lose a lot of business in the future, because the electrical undertakings are prepared to adopt systems by which the more the consumer uses the lower the price, to a very much greater extent than the gas industry is prepared to do. In such places as Manchester, where they have got what is known as the "Norwich" system—where electricity can be obtained for domestic purposes with a certain initial charge and at something like 1d. per unit afterwards—the fact that these people get away with it, and go on year after year, and make it pay, shows that they are not doing it for philanthropic purposes. They are not doing it to lose business, but they are doing it to gain business; and there is no question of immorality about it. It is business; and I do urge that an inquiry should be started to determine what are the practical means of differentiating between different charges for various purposes. I, personally, object to paying the top rate for gas when I use nothing but gas and coke in my own house, whereas the man next door, who uses no gas except a little for cooking, is charged the same rate.

Mr. S. SHADBOLT: The last speaker has reminded me that perhaps I allowed my feelings to carry me a shade further than I meant in using the word "moral." I meant that, when lighting consumers are over-charged, to subsidize power consumers who are directly under-charged, they are charged below the costs of generation, as has been proved. I consider, as a business proposition, that this is immoral. I was not alluding, of course, to high theology, or anything of that sort.

Mr. W. A. TOOKEY: It is needless for me to say that I have been extremely interested in Sir Dugald Clerk's admirable paper; but there is a saying that "fools step in where angels fear to tread," and I am going to dare to say that I think Sir Dugald Clerk has not been giving us quite a correct focus with regard to the rival methods of producing power. I think he will admit, when considering the figures of his table—I have only had the table a few minutes, and may be laying myself open to a retort which I shall thoroughly well deserve—that, particularly with regard to the production of producer gas from anthracite or coke, we can show for town gas a much better comparison, because the figures he has mentioned include no charges whatever for repairs or upkeep, so far as I read them. They include merely interest and depreciation on capital; but those of us who have had a considerable amount to do with suction gas producers will realize that the question of repairs should not be overlooked in comparisons of this sort. If this were not so, we should not find that so many users of suction gas plants, who adopted the fashion when it came in about 15 or 20 years ago, are now abandoning, in great number, these plants, and taking supplies of town gas, which they know is reliable and, all things considered, cheap. On the question of cheapness, I think that one cannot dissociate the question of service in connection with gas engines. I have been particularly interested in the President's remarks upon this point. I am not one of you gentlemen in the gas industry, as you know, but I am intimately connected with it, and I have first-hand information as to how town gas engines are working in various districts throughout the country. Only yesterday I was in a factory in London testing three small gas engines, each of them suffering from abnormal overloads; but, with all the difficulties of that kind, and the inefficiency which they meant, the owner told me that it paid him better to run these engines in that way to supply himself with electricity than to take a supply

of power from the public mains at the ordinary rates. Town gas has also been proved, in many districts in London, to pay in individual circumstances when proper accountancy methods have been adopted. Even kinemas find it very much better to make electricity from their own private generating plant, using gas engines; and there is always this advantage, that, apart from the convenience of town gas, there is the absence of standby losses, and the supply is ready at a moment's notice. There is also independence of industrial troubles from miners, railwaymen, and other people, because you have your eggs in your own basket, which is very much better than putting them in anybody else's; and this, of course, can be brought down to an £ s. d. factor of convenience *plus* cost. This is what I would recommend you gentlemen to study particularly. It would, of course, be inadvisable not to try to keep the charges for gas lower; but what I do, from my experience, offer to you as advice is that you should follow out the recommendations of your President this morning, and organize proper service for the engines working on gas. Then you will undoubtedly find your gas demand will go up, and particularly will it do so if you put the gas engine right down from the start, before the man has an opportunity to buy a second-hand gas engine from somebody else, which has already done useful service for a good many years, and has probably been erected by a man who is more like a plumber than an engineer.

The PRESIDENT: I am sure we are very pleased to have the remarks of Mr. Tookey; and I can endorse entirely what he says. In our case, if anybody wants to purchase a second-hand gas engine, we say that we do not recommend him to do it, and that it will pay him very much better to have a modern, up-to-date engine, because the saving in running costs and gas will be such that he will find it a better investment. With reference to Dr. Smith's remarks as to an inquiry concerning the selling prices of gas, that is a very difficult question; but I am certain that the British Commercial Gas Association will take notice of his remarks. If that Association can do anything to benefit the gas industry, he may be certain that they will do it. I may say that a number of gas companies, by their Acts of Parliament, are limited to a reduction of 25 p.c., for power purposes, of their selling prices for lighting. This, no doubt, can be got over, because, fortunately, under the Gas Regulation Act we have more elasticity. If we are to maintain the business, and increase it, the great thing, as Sir Dugald Clerk has pointed out, and as Mr. Tookey has emphasized, is that we must give service and reliability. This is the first consideration. Manufacturers want to be able to start their works at 8 o'clock in the morning, and run continuously until 5 or 6 o'clock in the evening, without any chance of breakdown, for 300 days in the year. We say in Derby that the manufacturers can do this, and, if there is anything wrong with their engines, within a few minutes our expert is at their works, and does what is necessary. I have great pleasure in asking Sir Dugald Clerk to reply to the discussion. I am not surprised that there has not been more discussion, because the paper is so complete, and has been dealt with by a master in regard to internal combustion engines. As Mr. Tookey seemed to be afraid to venture, I can quite understand you other gentlemen also being afraid.

Sir DUGALD CLERK: With regard to Mr. Helps, I am very pleased to find myself for once in agreement with him. We seemed to have some considerable differences a few years ago when I was President of this Institution; but now I am glad that he and I are to some extent in agreement. I notice that he still adheres to the fallacy for which he then stood up—namely, in taking the efficiency of gas production you must count the 70 therms that you get in actual gas, and, as you know, a ton of coal has about 290 therms total heat. That infers that you have lost 220 therms, but, of course, you have not lost the 220 therms, and that is where we differ. I allowed for the coke and the tar, and all the other substances that come into combustion; but Mr. Helps does not.

Mr. HELPS: That is purely a question of economics, and you are putting the case from the economical point of view. The coke very often costs more than you get for it. That is my point, but I do not think we had better start an argument.

Sir DUGALD CLERK: I do not wish to irritate Mr. Helps, but I do not agree that you should not take the therms from the total coal, and the total distribution of heat, which I have given you. You all know exactly my views on that matter, so I will not go into it any further.

Mr. HELPS again rose and endeavoured to speak, but was greeted with loud cries of "Order."

Sir DUGALD CLERK, continuing his reply, said: Mr. Walmsley has referred to the question of electrical distribution, and I agree that this enables you to put down separate motors. This is an enormous convenience in some works, and it is so great that the National Gas Engine Company, of which I have the honour to be a Director, have a central electric station driven by gas, partly by coal gas and partly by producer gas, and from that central station we are distributing electricity all through the works for cranes and machines and everything. I think the remedy for the state of things which Mr. Walmsley refers to is that, if you can sell gas at a suitable price, it will pay to generate electricity on the works by means of gas-driven machines. I have noticed repeatedly that this question of charging for electricity for power purposes arises. The figure given by Mr. Walmsley of 1·87d. per unit is about the average for the country, and, as he says, electricity is often sold at a 1¼d. for power. On the north-east coast it is sold at a lower price than this, but I understand the station costs there are lower. If you take the very large new electric power station in Manchester, the Barton power station, the efficiency of generation was proved by the Government returns last year to be 20·33 p.ct. That is, you have 20·33 p.ct. of the whole of the heat of the coal in the electric current. In some of the stations on the north-east coast it approximates to that, and you can even exceed it with a higher load factor. With regard to Mr. Shadbolt's remarks, I quite agree it is a pity that lighting consumers should be penalized for the sake of the power consumers; and it would be better if this could be avoided. The same thing applies in this case, of course—that you can meet many difficulties of this character by generating electricity on the premises. Dr. Smith, I think, is accurate in saying that it is very desirable that accountants should go into the matter of the financial division between the gas lighting load and the power load. I think it would be found, as he says, that there is a certain distribution of power load which you can with advantage supply at a lower price, for the reason which your distinguished President said—namely, that you have a steady weekly or daily load, and in that way there should really be no loss. In that case the superior morality of the gas industry over the electric industry would not be shocked by a lower price for gas for power purposes. [Laughter.] Mr. Tookey says, no doubt from his own experience, that I have not added to the suction gas plant the cost of repairs. I may say that the figures I have given you have come from the works. Possibly they may be taking an optimistic view, but so far as I can see they have no reason to charge that 10 p.ct. for repairs, which is really a very heavy charge, and I think you will find that the repairs are not so high as Mr. Tookey imagines. These are works figures, but I will go into them again to please Mr. Tookey.

Mr. TOOKEY: I am not thinking so much of works figures as users' figures.

Sir DUGALD CLERK: I cannot be responsible for users' figures, because users sometimes give you very surprising figures which, on investigation, often turn out not so accurate. I can appreciate Mr. Tookey's point, which he makes from a large amount of first-hand information, because he has tested many thousands of gas engines in actual work, as to the value of service. There is the necessity to readjust the valves and other things, to bring the engines up to maximum efficiency. Of course, the more recent engines are far more efficient than the earlier ones; and it is better for users who intend to put in gas engines to put in new ones, and not second-hand engines. I agree with both Mr. Tookey and the President on that point.

Mr. GEORGE HELPS: May I have half a minute now?

Loud cries of "No."

Mr. HELPS: Thank you very much. Good morning, gentlemen. [Loud laughter.]

The PRESIDENT: I know you will agree with me in thanking Sir Dugald Clerk for his very valuable paper. About a month ago I had a communication from Sir Dugald, who informed me that he had to go to Italy in consequence of Lady Clerk not being well, and he has been there for several weeks. Upon his return he was engaged upon some very important cases that occupied an enormous amount of time, and he was afraid that he would not be able to give his communication. I pointed out to him that this Institution would be intensely disappointed if he was not able to give this paper ["Hear, hear"]; and he then said, if it was the wish of the Institution that he should give a paper, he would do so. Therefore, we are all the more indebted to him for his very valuable communication, and I have the greatest possible pleasure, as President of this Institution, in proposing a hearty vote of thanks to Sir Dugald Clerk.

Mr. H. D. MADDEN (Cardiff): It gives me the very greatest pleasure to second the vote of thanks to Sir Dugald Clerk. It is not the first time that we owe a great debt of gratitude to him. Some of his investigations are standard works to which we refer whenever we want to strengthen our case, either in the conservation of coal or as regards the production of electricity. The paper is one, I think, which we shall take away and think over, because there are many points in it which we shall require to study in regard to power production.

The vote of thanks was carried with acclamation.

Sir DUGALD CLERK: Mr. President and gentlemen, I thank you.

THE ECONOMICS OF GAS PRODUCTION ON THE THERMAL BASIS.

By GEORGE EVETTS, M.Inst.C.E., M.Cons.E.

The passing of the Gas Regulation Act, 1920, has enforced a new basis of comparison in gas production, distribution, and finance. The word "enforced" is used advisedly, as it must not be overlooked that for many years previously the thermal basis had been given serious consideration by many gas engineers, who realized that the volume basis was no longer the sound method of comparing either working or financial results. These pioneers voluntarily accepted the new standard of assessment, and new developments were viewed from the thermal standpoint. In fact, some companies promoted legislation whereby gas was sold with a defined minimum calorific value.

The Standard of Calorific Power Order made the procedure so simple that many undertakings accepted the calorific standard, which conferred substantial benefit on those who were in a position to take advantage of it, and whose candle-power standard was 14 or over.

These were only milestones on the road of progress, however; and it is clear now that the universal standard of 500 B.Th.U. or the special calorific value prescribed in the respective Acts of Parliament of the pioneers did not give the necessary elasticity to enable an undertaking to get down to rock bottom in costs of production and supply. Immediately the need for elasticity in manufacture became appreciated and recognized, it was apparent that the volume basis of sale must give way to the conception of selling thermal units in a more or less condensed form, leaving the strength to be settled by each individual supplier. There were some who preferred gas still sold on the volume basis at a guaranteed strength, using the standard therm price only as a medium for the calculation of dividends, but this method would have destroyed the element of simplicity which now exists.

The therm provides the universal standard of comparison; and as the gas industry is marketing therms, this is the basis to which all costs must ultimately be reduced. Calculations based on the volume of gas or the tonnage of coal are only useful in so far as they deal with the plant or machinery handling such volume or tonnage, and to this extent affect the working costs. Finally all results and costs must be reduced to the therm. This is sometimes lost sight of when considering (for example) claims of rival carbonizing systems. A motor-car maker only considers the amount of steel used or number of employees engaged so far as such information helps him to calculate the number of cars which can be made; but all his prices and comparisons must ultimately come down to the costs per car manufactured and sold. Therefore, the gas maker must first consider the known or likely demand for therms, and calculate his requirements accordingly. He cannot boost or retard this demand to any appreciable extent by ringing changes on the calorific value. If this were possible, then the freedom which the Act allows would be a fraud on the consumer.

Many discussions have taken place on the variation in the volumetric sale due to changes in calorific value, and somewhat remarkable statements have been made to the effect that chosen typical consumers have used the same volume, or even less, of low-grade gas, compared with corresponding periods when a higher grade was supplied. It is difficult to criticize these statements without full knowledge of the facts, but the author is of opinion that they would not bear investigation.

Tests on individual appliances have proved that, within fairly wide limits, the efficiency is approximately constant, or, to use the common expression, "one B.Th.U. is as good as another." Sometimes we are expected to believe that one cubic foot is as good as another. Now, what is true in the individual must be true in the aggregate; the author has made inquiries into the records of typical groups of consumers, and has found that the results are most conflicting. Therefore any theory could be promulgated by picking-out certain cases for quotation.

In dealing with upwards of ninety cases of applications for Section 1 Orders, the author has formed the opinion that, broadly, the volumetric consumption increases as the calorific value decreases. In one illuminating example, the calorific value was 540 (or thereabouts) in 1913, and 375 in 1921. The sale in the meantime had increased by over 50 p.ct. In other words, 540 therms sold in 1913 had risen to 565 in 1921, and the thermal sale per consumer was practically unaltered. The example formed a useful comparison, since there had been very little building work, no violent fluctuations due to munition work, and there is one staple industry on which the prosperity of the inhabitants depends. The position in this particular industry was unaltered, and, therefore, the comparison could be based on stable conditions. In the case quoted, the records of typical consumers were of no value in leading to definite conclusions.

The basis of all calculations, therefore, is the demand for thermal units; but, having got so far, the gas maker cannot dissociate the volume from his considerations. The volume of gas is the vehicle or medium by means of which the therms are carried, and a therm is intangible unless associated with the volume. The manufacturer of gas must produce a predetermined volume, and the distributor is called upon to propel this volume up to the point of ignition, with a certain flexibility at that point, but very little flexibility between that point and the gas-works.

To use the simile of whisky, if a distiller were permitted to choose any grade of liquor he wished, and sell on the basis of proof-spirit, he would, in preparing estimates of cost, find it necessary to take into consideration the size of the bottles and cases he would need to market the liquor, and the cost of transporting it to the homes of the consumer.

In the gas-works, the producer is given a large range in the carbonizing plant, both in volume and strength; but at this point the flexibility ends when considered on the volume basis. Exhausters, washers, scrubbers, purifiers, gasholders, and works mains are limited in regard to volume. Taking the gasholders as a case for comparison, assume that the maximum daily demand is 10,000 therms (1·82 million c.ft. of 550 gas), gasholder storage of 1,600,000 c.ft. would represent 8800 therms, or 88 p.ct. of the maximum day, with a 550 B.Th.U. declaration; but if the quality were lowered to 400, the thermal storage would be reduced to 6400 therms, or 64 p.ct. of the maximum. In order to reach 88 p.ct., as before, additional storage of 2400 therms, or 600,000 c.ft., would be necessary—costing about £15,000. This would add 1·4d. per therm to the capital cost per therm sold per annum (based on 250 maximum days per annum). The same would apply to a lesser extent to the other items of plant mentioned.

In the distribution plant the volume of gas to be handled would also be increased, with the added disadvantage that the specific gravity would be higher; and the combined effect might be that mains would need to be increased in size, with the result that additional capital charges would more than neutralize any saving effected in manufacture by the reduction in calorific value.

In matters of selling and administration, therefore, cubic feet can be discarded, but in manufacture, distribution, and measurement, the volume must be considered in conjunction with the heat units contained in that volume.

The following factors must influence the choice of the declared calorific value, whether it be the first or a subsequent change:

(1) The grade likely to give most satisfaction to the consumers; the special demands (if any) of trade and industry.

(2) The class or classes of coal available, and the relative prices delivered.

(3) The relative values of coal, oil, and residual products.

(4) The capacity, type, and condition of the carbonizing plant—viz., the efficiency.

(5) The capacity of the remaining portions of the works plant.

(6) The capacity and condition of the distribution plant.

(7) The latest developments in carbonizing plant and manufacturing processes.

(8) The operating costs of the various types of manufacturing plant, either existing or proposed.

(9) Capital costs and rate of interest on money in cases where new plant is under consideration.

Circumstances differ so widely that it is impossible to state the relative importance of the nine factors enumerated. Fortunately, a close financial estimate can be prepared of the effects of the governing factors except those numbered 1, 2, 3, and 7. In the case of items 2 and 3, a close estimate can be made of the conditions at the time of making the decision. Item 7 can be estimated with a reasonable degree of accuracy based on known results elsewhere or on makers' guarantees, leaving only the first, to which no numerical calculation can be attached. Past experience is usually the guide, and the combined skill of the purchasing, manufacturing, distributing, and selling staff is necessary to arrive at the right decision.

These nine factors will now be considered in order:

(1).—The Satisfaction of the Consumer.

The experience of the past few years has enabled many companies to gauge accurately the calorific value which is most acceptable to the consumers. It has frequently been observed that complaints begin and end within a comparatively narrow margin of calorific value. Whether these complaints are due to the insufficiency of the trunk mains, service pipes, or pipes on the consumers' premises is of some importance, for, if the change in calorific value necessitates wholesale alterations to mains and services, then a change is obviously undesirable. The same applies to the frequency of naphthalene troubles. If a change effected in the method of manufacture with a view to the alteration of calorific value seriously increases naphthalene trouble, it would be unwise to contemplate the change. As far as the appliances are concerned, it may be accepted as a general proposition that, if the pipe leading up to the appliance is capable of dealing with the necessary volume of gas having the proposed calorific value, then the adjustment of the appliance itself is a comparatively simple matter within wide limits. The nipple can be adjusted, and the pressure at the point of ignition can be increased or reduced, in accordance with the grade of gas supplied.

As previously mentioned, in deciding upon a calorific value it must be assumed that the demand in thermal units will be fixed, and independent of the grade; the efficiency of the appliances is constant within wide limits of value, and therefore no consideration of increased or decreased total sales should affect the decision.

The financial effect of this is to stabilize the standing charges per therm, whatever may be the declared value. It is necessary to emphasize this, as the author has heard it stated that, as the standing costs per 1000 c.ft. of gas are not affected by the quality, the richer the gas the lower the costs per therm. This would be true if the same volume of gas could be sold, but the increase in calorific value would automatically reduce the volume, and the costs per 1000 c.ft. sold would be higher before the conversion to costs per therm. In other words, the standing costs per 1000 c.ft. are affected by the quality.

It is equally important, however, to choose a value which will result in the thermal units being conveyed to the appliances of all consumers at the rate necessary for efficiency. The time element is as important to the domestic as to the industrial consumer. Complaints are made that the gas is bad, but the gas official knows that the real complaint is lack of pressure, preventing the consumer from getting the thermal units per minute or per hour which he wants. The result is doubly bad—the gas sales are curtailed and the consumer is dissatisfied.

From the experience gained during the past five or six years, there seems little doubt that the higher the value, within defined limits, the greater the satisfaction, assuming that the appliances are adjusted to deal with the gas without the dirt and waste indicated by carbonizing-up. Reducing the value *might* cause difficulties, but increasing it should not.

(2).—The Class of Coal Available.

The question of coal must be associated with the values of residual products and the type of the carbonizing plant—viz., items 3 and 4 in the list of factors.

If cheap coal is procurable from neighbouring coalfields, and the plant is capable of dealing with such coal, then the volatile matter and ash content compared with the price is a useful guide only if the coke yield is satisfactory in amount and quality. As the value of residual products gets less, so do the gas-producing qualities of the coal become of increasing importance.

To trace the effect of reduction of quality in coal or coke, take a simple case of two coals:

(*a*) Producing 63 therms per ton, and costing 28s. 6d.

(*b*) Producing 70 therms per ton, and costing 32s. 6d.

Now, if in each case the bye-products fetched 67 p.ct. of the coal cost, the net coals would be:

$$(a)\ \frac{33 \text{ p.ct. of } 28\text{s. } 6\text{d.}}{63} = 1{\cdot}79\text{d. per therm.}$$

$$(b)\ \frac{33 \text{ p.ct. of } 32\text{s. } 6\text{d.}}{70} = 1{\cdot}84\text{d. per therm.}$$

If, however, the coke from coal (*a*) fetched 2s. per ton less, the difference is 1s. per ton on net coals, and 67 p.ct. becomes reduced to 63½ p.ct., and the costs would be:

$$(a)\ \frac{36\tfrac{1}{2} \text{ p.ct. of } 28\text{s. } 6\text{d.}}{63} = 1{\cdot}99\text{d. per therm.}$$

$$(b) \qquad\qquad = 1{\cdot}84\text{d. as before.}$$

Therefore, the balance would change in favour of class (*b*).

If residuals produce a very large proportion of the coal cost, then the question of therms per ton is not so important, and a cheaper coal turning out less therms per ton might be more economical. For instance, if 20s. per ton of coal carbonized were to be obtained for residual products in the case of either of two coals, then a good coal at 30s. producing 70 therms would be less advantageous than poor coal at 26s. producing 60 therms.

$$\text{Net coal costs for good coal} = 10\text{s.} = \frac{120\text{d.}}{70} = 1{\cdot}71\text{d. per therm.}$$

$$\text{Net coal costs for poor coal} = 6\text{s.} = \frac{72\text{d.}}{60} = 1{\cdot}20\text{d. per therm.}$$

(3).—Relative Values of Coal, Oil, and Residual Products.

From the last few remarks it is clear that immediately coal quality comes under discussion it is impossible to keep clear of the effect of residual products.

After remaining stable for a couple of years, coke has unfortunately decreased in price substantially during the past twelve months. The receipts for tar and liquor also compare very unfavourably with 1923. The amount of tar and liquor produced per ton of coal is of comparatively minor importance in the cost of gas, though the prices received can be by no means neglected, seeing that the net receipts amount on the average to ¾d. per therm.

As Mr. Evans has pointed out in his Cantor Lectures, the thermal balance-sheet does not assume full importance unless the financial value of the therm in gas, coke, and tar is considered. To quote an absurdity, a process giving 95 p.ct. efficiency would be of practically no value if only 5 p.ct. of the yield was in the form of gas. In fact, a plant with 50 p.ct. efficiency, of which 25 p.ct. was gas, would be better financially.

The following may be said to represent fairly the value in the London district at the present time:

Coal at 32s. per ton = 1·28d. per therm.
Coke at 30s. per ton = 1·28d. per therm.
Tar at 3½d. per gallon = 2·00d. per therm.
Gas cost into holder = 4·50d. per therm.

On this basis, every therm produced as gas is nearly four times the value of a therm in coke, and over twice that in tar.

The following would represent the commercial value of a process per ton of coal handled:

$$\text{Value} = 4\tfrac{1}{2}\,t + 18\,c + 3\tfrac{1}{2}\,g$$

Where t therms of gas are produced at 4½d.,
c cwts. of coke are produced for sale at 1s. 6d.,
and g gallons of tar " " " " " 3½d.

This short cut would only apply, of course, where the same qualities of coal are dealt with at approximately the same prices.

In considering the value of residual products in relation to coal, the gas engineer is so familiar with net coal calculations that he knows the figure to which coke can drop before it pays to make water gas, and also the figure to which it can rise before he need seriously consider the question of dropping his "make" in order to have more residual products to put on the market. There may come a time when he must change his point of view, and regard himself as a producer of coke and tar. He could then afford to reduce his make per ton up to the point where

the plant would no longer deal with the tonnage of coal, or the market no longer absorb the residual products. The advantage under the Gas Regulation Act is that this lower make per ton would be richer, and consequently a higher value could be declared; and if this condition of affairs showed any prospect of permanence, it would pay to increase the declaration.

During 1921 the author, in dealing with a small undertaking making less than 20 million c.ft. per annum, found that the net coals were *nil*, due to a good local market for coke and tar, and it actually paid better (even on the volume basis) to make 10,000 c.ft. per ton rather than 12,000 c.ft. This would become more pronounced when selling gas on the thermal basis.

In cases where the residual products yield is stable in quantity, the financial result depends on residual prices; and the usual return from bye-products may vary from 50 to 80 p.ct. of the net coals, dependent on the selling prices. In these circumstances it is clear that, in the case of coal gas, the cheapest method of manufacture is that which produces the largest number of therms per ton of coal (leaving water-gas reactions or any steaming or similar combination out of the matter); and such method would cheapen costs in so far as the amount of solid fuel dealt with (coal and coke) is accordingly reduced.

In reference to coal gas manufacture without steaming, the decision is a simple one, whether the calorific value or the cost of manufacture is considered. The relative value of coal, oil, and residual products comes more into the picture when the steaming of vertical or horizontal retorts is under consideration, in contrast with the manufacture of water gas as a second-stage process.

It may be accepted without investigation that, in normal times (in fact, any time during the past five years), coal gas is cheaper than water gas, and a low-grade gas is more costly to produce per therm than a high-grade, if the lower grade is a result of water gas admixture, either blue or carburetted. In the case of steaming, the thermal increase is made at the expense of the coke yield, but at no cost for wages, very little for repairs, and only a small addition for fuel in the absence of waste-heat boilers.

In reference to complete gasification, the margin becomes very much narrower unless the financial yield from bye-products is uniformly good. Take, for example, a plant yielding 66 therms per ton with coal at 32s. and bye-products returning 80 p.ct. of this cost. The net coal cost is 6·4s. per ton, or 1·07d. per therm. A complete-gasification plant producing only a little tar and 180 therms per ton would result in a net coal cost of gas of 2d. (or thereabouts) per therm. However, if the yield from bye-products is reduced to 60 p.ct. of the cost of coal, then the complete-gasification plant would be cheaper.

With regard to the costs of water gas admixture, it is simple to construct graphs showing at a glance the point at which it pays to make water gas, either blue or carburetted. The economics of carburetting will be discussed later.

The relative value of coal and residuals does not seriously affect the costs of production between narrow limits of calorific value, but is material in considering the relative costs between high and low grade, where the latter includes the carbonization of the resultant coke, or complete gasification in one stage. It can be readily appreciated that, with relatively cheap coal and dear residuals, the high-grade gas is the cheaper to produce, and, with relatively dear coal and low residuals, the lower grades become cheaper, whether made as a result of complete gasification in one stage, or by steaming, or by producing water gas in a separate generator.

With any given price of coal, complete gasification will not pay (taking only net materials into consideration) if more than 60 p.ct. is returnable for residual products. This figure is based on the following assumptions :

1. That the fuel for carbonizing in one stage is paid for by the tar, &c., from the process.
2. That 180 therms per ton of coal are obtainable from complete gasification, and 70 therms from retorting.

180 represents 100 p.ct. of cost of coal.

70 represents 39 p.ct. of cost of coal (*i.e.*, net coals).

In the same way, it can be deduced that, with coke standing at or above 80 p.ct. of the price of coal per ton, it does not pay to make water gas, basing the make at 42,000 c.ft. per ton for generators and blowers. As a general rule water gas does not pay if 55 p.ct. or more of the cost of the coal is obtained from residuals.

It may be stated, therefore, that a low coke market should encourage the production of lower grades of gas.

Cost of Blue Gas and C.W. Gas.

At first view, carburetted water gas is much more costly than blue gas; but the net materials *plus* wages do not represent the total cost of these gases. Given a carburetted plant, it is cheaper to make carburetted gas; but if the gases can be made in separate plants, the respective efficiencies must be considered. The following table shows how the costs of blue and carburetted gas would compare if all factors are introduced. The coke figures and oil figures of yield are taken from Dr. Parker's paper on "The Production of Different Grades of Gas," read before the North British Association of Gas Managers, in September, 1924.

	Blue Water Gas. 840 C.Ft. 292 B.Th.U. = 2·45 Therms.			C.W. Gas. 1000 C.Ft. 483 B.Th.U. = 4·83 Therms.			Typical Coal Gas.
		Per 1000 C.Ft.	Per Therm.		Per 1000 C.Ft.	Per Therm	Per Therm.
	d	d.	d.	d.	d.	d.	Coals. d.
Coke, 36 lbs. at 30s. ton	5 8	6·91	2·37	5 8	5 8	1·20	5·00
Boiler fuel, 10 lbs. at 20s. ton	1·1	1·31	0·45	1 1	1 1	0 23	..
(not necessary if waste-heat boilers)							
Oil, 1·84 gallons at 5¾d.	..	..	..	10·6	10·6	2·19	..
Wages and salaries . .	3·0	3 57	1 22	3 0	3 0	0 62	0·80
Purification	0·3	0 36	0·12	0 5	0 5	0 10	0·11
Repairs to water gas plant	2·0	2·38	0·82	2·0	2·0	0·42	0·85
Repairs to general plant	3·4	4 05	1·39	4·0	4·0	0·83	0·85
	15 6	18 58	6 37	27·0	27 0	5 59	7·61
							Residuals.
Less oil, tar, 0·2 gallons at 3d.	..	..	..	0 6	0·6	0 12	3 20
	15 6	18 58	6 37	26 4	26 4	5·47	4·41

Each gallon of oil adds $\frac{2·38}{1·84}$ therms = 1·29 therms.

In the above table it will be seen that, for an extra expenditure of 10·8d., we obtain 2·38 therms, or 4·53d. per therm, against 6·37d. per therm, as the original cost of blue gas.

Each penny reduction in the gallon of oil would reduce the cost of carburetted gas by 0·4d. per therm.

Each 2s. per ton in the value of coke accounts for 0·16d. per therm in the value of blue gas, or 0·08d. per therm in the oil gas; or 10s. per ton reduction in coke has only the same effect as 1d. per gallon in oil. The effect of 1d. per gallon drop in oil and 6s. per ton in coke would bring the coal gas equal in cost to C.W. gas, having regard to the increased cost of coal gas.

Therefore, if more therms are required from the combined plant, they are available in the water-gas plant, without one penny expenditure for capital, either in carbonizing or general plant, and at a cheaper rate than blue gas or gas very slightly carburetted. In the above table it is assumed that the additional thermal production is required, otherwise the fixed expenditure on wages would be divided over a smaller thermal output, and consequently be of no financial advantage. The table is also based on the assumption that the blue gas is made in a carburetted plant. If not, then the coke figures must be adjusted to the probable consumption. Such adjustments would only affect the difference; and it may be assumed that the cost of obtaining therms by carburetting will always be cheaper than the original blue gas. It is seen that, for carburetted gas, coke per therm is about half as much as for blue gas. The capital costs are not included in the table, otherwise the difference would become greater.

To sum-up briefly, therefore, it is safe to assume that, on present costs :

(*a*) Coal gas is cheaper than either blue or carburetted water gas.

(*b*) Carburetted water gas is cheaper than blue gas, into the gasholder.

(*c*) Complete gasification at 180 therms per ton is equivalent to coal gas when 60 p.ct. of the cost is obtained from residual products (after adjusting for fuel for carbonizing in the former).

(*d*) The cheapest coal gas to make is that giving the most therms per ton of coal in normal circumstances.
(*e*) The above factors tend to produce cheaper costs in higher declared values.
(*f*) Low coke prices tend to lower calorific values.

(4) and (5).—THE CAPACITY AND TYPE OF EXISTING PLANT.

As previously mentioned, the plant must be considered in conjunction with the prices of coal and residuals. A 100 p.ct. coal gas might be the right thing on paper; but if the coal gas plant is incapable of producing the full requirements, then the figures are only of value when considering the desirability of erecting additional plant for coal gas. The relative costs of the past two or three years have proved the desirability of having sufficient coal gas to meet total requirements. Everyone has not been in this fortunate position, but the lucky ones have been able to save at least the capital and sinking fund charges on water gas or extraneous plant used only in emergency. The emergency value of water gas must not be overlooked, and it is good practice and good economics to use retort houses or sections of retort houses to their fullest extent, producing thermal units with such labour engaged as is necessary and no more than necessary for the complete unit. Emergency demands or even seasonal demands of short duration can be met most cheaply by making water gas of value approximately equal to the coal gas.

The type and condition of the plant are generally the decisive factors in arriving at a decision on the nature and quality of the gas; but, in spite of this, there are comparatively wide limits of calorific value open for choice. Practically any known system has a variation of over 100 B.Th.U. per c.ft. The condition of the plant must be taken into consideration, but the performance in any set of conditions can usually be closely estimated by the responsible officer.

The maximum production of therms per ton is not always the cheapest method of production when everything is considered. One therm of gas is as valuable as $\frac{1}{6}$ to $\frac{1}{4}$ cwt. of coke, as it is produced at no increase in the labour costs, and very little for repairs. It is possible, therefore, that the maximum make of therms per retort in the house may be more economical than maximum therms per ton. The models prepared by Mr. Evans in his Cantor Lectures showed very clearly the thermal value of the gas produced at all stages of the distillation process, and it was obvious that the last two therms or so might easily be made at the expense of throughput or to the detriment of the ultimate cost of gas. When the volume only was of consequence, the additional gas appeared of more importance.

In a recent case in the author's experience, an undertaking was getting short of carbonizing power on the coal gas side, and water gas was more costly to manufacture. The problem was to increase the throughput of therms per day; and it was decided to face the consequence of reduced therms per ton. The duration was consequently changed from 12 to 8 hours, and the charges reduced by about one-fifth. It was anticipated that the make would be reduced by about 3 therms with an increase in coke for sale, due to the fact that the fuel required would not increase correspondingly with the coal throughput. The comparative figures of coal carbonized were :

Before the change, 2 per day × 12 cwt. = 24 cwt.
After the change, 3 per day × 10·5 cwt. = 31·5 cwt.
i.e., an increase of 31 p.ct.

The therms per ton dropped from 72 to 68½, but the coke increased from 10 to 10·6 cwt. for sale, as the fuel in the furnaces was not increased by more than 5 p.ct. The make per retort in therms, therefore, was increased from 1·2 × 72 = 86·4 therms to 1·575 × 68½ = 107·9 therms—an increase of 25 p.ct. After equalizing coal and residual prices, it was ascertained that there was a slight saving per therm on the repairs and wages, with the result that the gas into the holder cost 4·5d. per therm after the change, compared with 4·63d. per therm before. This is not a substantial saving; but the percentage of coal gas was increased from 75 to 87, and the total cost of the mixed gas is as follows, again adjusting prices to the same level :

Before.	After.
75 p.ct. coal gas at 4·63d. = 3·41d.	87 p.ct. at 4·50d. = 3·91d.
25 p.ct. water ,, at 6·07d. = 1·52d.	13 p.ct. at 6·07d. = 0·79d.
4·99d.	4·70d.

Hence the total over-all saving is 0·29d. per therm, and the increase in output has postponed for three years a capital expenditure of at least £25,000, representing 0·17d. per therm in interest and sinking fund over the whole output.

In another case the declared calorific value was 475 B.Th.U., and the quality actually made about 485. The maximum daily production was 1·9 millions, or 9125 therms on the made value; the annual make being 2,210,000 therms. The question of increased carbonizing power was under consideration, as well as a proposal to increase the calorific value, with the result that costs were closely investigated. The maximum working power of the retort houses was 7900 therms, with one empty arch for 8 through retorts for further development, leaving 1315 therms made in the water gas plant by 400,000 c.ft. of 340 B.Th.U. gas. Eight-hour charges were in operation, and it was ascertained that no further savings or increase of throughput could be obtained.

The next step was to ascertain the cost of increasing the calorific value by maintaining the thermal make of coal gas, but taking-up the increased sale by raising the declared value from 475 to 500, or the quality manufactured from 485 to 510.

The comparative figures worked out as follows :

—	A. 475 Declared. 485 Made.	B. 500 Declared. 510 Made.
	Therms.	Therms.
Annual make coal gas . . .	1,900,000	1,900,000
Annual make water gas . .	310,000	424,000
	2,210,000	2,324,000
Increase	..	5·2 p.ct.

The additional therms from water gas amount to 114,000, and the plant was capable of producing this without increased labour, by the addition of oil; and at 1¼ therms per gallon the cost was $\frac{114,000}{1\frac{1}{4}} \times 6\text{d.} = £2280$ per annum, or 4·8d. per therm made, which was less than the cost of the gas then being delivered to the holder. The over-all saving was estimated at £810 per annum. The actual increase in sale during the succeeding year was 5 p.ct., so that the additional bed of retorts was not required, but was set for the following winter, raising the coal gas power to 8500 therms per day. A further increase in the volume of water gas was contemplated, the cost per therm of which would be a little less than the water gas then being made. With a further slight increase in the calorific power of the water gas, the power of the works would be :

Coal gas	8,500 therms per maximum day
Water gas	2,750 ,, ,, ,, ,,
	11,250 ,, ,, ,, ,,
Compared with . . .	9,215 therms originally, or an
Increase of	22 p.ct. (say) four years' growth.

Since these estimates were made, however, the disparity between water gas and coal gas costs into holder has been increased, with the result that, if all coal gas could be made, the cost would be about 4·76d. per therm, and if made according to the above programme, the cost would be 4·97d. per therm—a difference of 0·21d. per therm.

The carbonizing plant proposed would obviously have to be built too large for immediate necessities, and the total cost would be approximately £22,500. The interest charge would be £1460 per annum, or 0·16d. per therm. So that, instead of producing a saving as originally anticipated, the increase as water gas is proving a little more costly, as the point has been passed where the increased thermal make can be effected by the mere addition of oil. However, the difference is even now only 0·05d. per therm more than the interest on the estimated capital expenditure, so that the programme has not been a failure.

If the existing plant were inefficient, and a new plant offered distinct advantages in efficiency and running costs, then a new factor would be taken into account; but this was not the case in the plant referred to.

With reference to the efficiency of carbonizing plants in general, they must be judged entirely on their merits according to known results and the proposals put forward by competing contractors; but it may be of interest to investigate the financial results of the methods of carbonizing summarized in Dr. Parker's paper to the North British

Table of Net Coal Costs.

Association of Gas Managers previously referred to, as well as other systems.

Two bases are taken, the second showing a lower return for residual products.

The first eight items in this table should be used for making comparisons only within limits. The Lanarkshire washed nuts produce only 9670 c.ft. of 600 B.Th.U. gas, or 58 therms per ton, with 8·1 cwt. of coke for sale, when carbonized in horizontal retorts. It would appear either that this is an unsuitable coal for horizontals or that the horizontal retorts were not in a good condition, for when carbonized in vertical retorts 9·4 cwt. of coke were produced, with 67 therms of gas.

The unreliability of the thermal balance from the financial point of view, even when dealing with the same system and plant, is shown in comparing lines 1 and 2. The thermal balances of these two are almost equal, whereas line 2 produces gas about 30 p.ct. cheaper than line 1, due to the therms in the gas being of more value than the therms in the coke.

It will be seen that the extra therms produced by steaming are much cheaper than obtaining additional therms either in a blue water gas plant or by carburetting; in fact, the steaming of vertical retorts probably represents the cheapest method at present known of obtaining increased output. The figures are on the assumption that the coke from the steamed verticals is of the same value per ton as unsteamed.

The results for low-temperature systems show-up very favourably on the prices given; and if the yields can be guaranteed, coupled with a market value of 5s. per ton in excess of coke for the solid fuel, there are decided attractions in most systems. In the last four calculations, a small part of the solid fuel is taken at breeze prices. The tar is taken at 1½d. per gallon more than in the first part of the table, to include the additional value of spirit obtained. There is a substantial increase, however, in the cost of gas for 2s. 6d. decrease in the receipts for the semi-coke. It will be observed that in the Parker process it amounts to 0·53d. per therm, compared with half this amount in vertical or horizontal systems. Similarly a penny loss in tar per gallon amounts to 0·47d. per therm in the gas, compared with 0·15d. in the case of the existing methods. Thus 2s. 6d. a ton difference in coke (say, half this amount in breeze) and 1d. per gallon in tar affects the cost of gas as follows:

Parker process ... ... 0·73d. per therm.
Verticals with 20 p.ct. steaming ... 0·23d. per therm.

There is little to be added regarding the capacity of the works plant other than carbonizing. Practically the whole of the plant outside the retort house is limited in capacity on a basis of volume; and consequently the richer the gas the more economical will this part of the plant be to construct, operate, and maintain. Fortunately, the capital or running cost does not increase in proportion to the volumetric capacity, and it is real economy to construct plant well ahead of requirements.

(6).—The Capacity of the Distribution System.

Distribution problems in relation to calorific value have been fully discussed by able writers, so that only a brief note is necessary. Whatever may be the differences of opinion regarding methods of manufacture, there is no

doubt that the high-grade gas is favoured by the distribution engineer, for the following reasons:

1. Less pressure is required to deliver thermal units in a highly condensed form, due to the less volume to be dealt with. Alternatively, the same works pressure gives a better pressure to the consumer.
2. The lower volume is associated with a lower specific gravity.
3. The higher grade keeps the mains and services more free from corrosion, and therefore their carrying capacity is maintained.
4. The higher grade is usually associated with a higher saturation point, and naphthalene is less troublesome.

There is no doubt, therefore, that economically the higher grade scores on all points.

It is frequently argued that the distribution difficulties can be solved by increasing pressure at the works, but the fact remains that with a higher quality the increased pressure would deal with still more gas, so that a main of given size has a reserve of potential power if the calorific value is increased. Boosting gives rise to unequal pressures, and 12 in. near the works coupled with a bare 3 in. at the distant points cannot be desirable.

The increase of the minimum pressure prescribed by the Act of 1920 is only of practical importance in certain areas, as the gas undertaking previous to 1920 always aimed at a pressure in excess of 2 in. in the service pipes. In the areas affected, however, the problem is none the less a serious one, and the cure is usually a costly one.

The importance of the quality is clearly shown by taking typical cases. In a paper read before the Public Works and Transport Congress in 1923, Mr. H. E. Bloor compiled a comprehensive list of gases supplied by various undertakings; and the lowest in the range was 290 B.Th.U., and the highest 564 B.Th.U. Adopting Pole's formula, the pressure drop along an 18-in. main 3600 yards long delivering 500 therms per hour is shown in the following table, and the delivery in therms per hour with a fixed pressure drop of 2 in. is also given, together with the next lowest gas in the list (412 B.Th.U.).

B.Th.U. Gross per C.Ft.	Sp. Gr.	Pressure Drop at 500 Therms per Hour.	Delivery with 2 in. Pressure Drop, C.Ft. per Hour.	Delivery with 2-in. Pressure Drop, Therms per Hour.
290	0·59	180 tenths	57,000	166
412	0·62	95 tenths	55,700	229
564	0·40	33 tenths	69,200	390

No comment is necessary; the figures point the moral.

In connection with the supply mains in general, increasing attention is being paid to distribution holders at outlying centres of population. It is frequently found that the maximum hour is one-seventh of the day, and that 60 p.ct. of the gas is taken in six hours. The construction of outlying holders at balanced pressure results in working the mains for 24 hours a day (16 hours feeding and 8 hours supplying), with the result that their capacity is more than doubled.

Taking an example within the author's knowledge, an outlying village six miles from the gas-works, taking about 25 million c.ft. a year, has a maximum day of approximately 100,000 c.ft., and the pressure at peak hours drops to 25 or 30 tenths in the main street. The mains at the gas-works are 24 in. reducing to 18 in., and the last four miles are in 12 in., but the demand in the first two sections is naturally heavy.

A new holder of 70,000 c.ft. capacity is under construction, costing £4000, and ensuring a pressure of 48/10ths in the centre of the outlying supply, whatever may be the demand in the principal district. If the demand in the principal district increases by nearly 100 p.ct., the position in the outlying district is still secure. A 12-in. main would cost about £2700 a mile; and, therefore, the holder is put up at a cost of 1½ miles of main with no boosting expenditure. This does not represent the full advantage, however, for the increased holder storage reinforces the works storage to exactly the same extent, and provides for an increased business of nearly 25 millions. Therefore, the increased capacity of the main has been achieved at what is, in fact, very little additional cost, with the accompanying advantage of a constant pressure independent of what is happening in the populous part of the district.

(7).—Latest Development in Manufacturing Processes.

The newest methods of gas production do not actually call for detailed examination until additional plant is required. It is rare that any innovation offers such an overwhelming advantage as would justify scrapping comparatively new plant. Gradual replacement is always accompanied with improvement, and the "old-fashioned" systems are improved from time to time, with the result that, where new plant is necessary, the comparison is not between the existing plant and the latest innovation, but between the latest in all systems. Fortunately for the capital account, partial reconstruction, or even repairing, can be utilized for improvements in existing systems. The four main factors to be considered are:

(*a*) Net coal costs.
(*b*) Capital costs.
(*c*) Repair and maintenance costs, usually dependent on (*b*), since a low capital cost is generally associated with low renewals.
(*d*) Wages and operating costs.

During the past few years two methods of carbonizing have been developed for town gas manufacture—complete gasification and low-temperature carbonization.

Complete Gasification.

There is no doubt that complete gasification has come to stay. It is flexible, and the two systems previously referred to can be utilized to produce gas of considerable variation. In all the points mentioned above, the costs, when reduced to the thermal basis, are low. In general, it may be expected that any process giving a large thermal yield per ton of coal handled will produce low operating and repairs costs per therm; and this is intensified where there is no solid bye-product to handle.

Mr. Robinson, of Harrogate, gives the repairs for his plant at 0·11d. per therm, against 0·21d. for the horizontals; and the wages at 0·2d., against 0·4d. for horizontals, presumably compared on the same basis.

The wages on the Tully plant at Halifax are given as 0·55d. to 0·6d. per therm, including carbonizing and clinkering.

Low-Temperature Carbonization.

Low-temperature carbonization has yet to prove its claim as an accepted business proposition in gas-works; but there have been substantial improvements in recent years. It is obvious that the success of any system must depend primarily on the willingness of the public to purchase the resultant fuel at a price which compensates for the lower thermal production; and, secondly, the capital cost and working expenses must be reduced. The former of these secondary factors is more difficult of realization than the latter, having regard to the large amount of coal to be handled and distilled in relation to the thermal yield.

Contrasting extreme methods, complete gasification offers low capital with gas yields amounting to 140 to 180 therms per ton. Low temperature pure and simple is the reverse, as the constructional parts must deal with a heavy throughput with a yield of only 40 to 60 therms per ton, with no compensating speed of distillation.

For this reason the trend of modern invention is in the direction of admixtures with producer and water gas; and it would appear that success is likely to be achieved on these lines, using the heat as far as possible for internal carbonization.

If the public can be converted to the advantages of smokeless fuel, there will still remain the competition between gas coke at (say) 8s. per ton less than coal, and low-temperature coke up to 5s. per ton more than coal. Experience has taught low-temperature advocates that there is no advantage to be gained by carbonizing poor coals with high ash content.

At the Smoke Abatement Society's conference at Manchester in November, 1924, there were three papers dealing with the subject; and an analysis of the claims made will be of interest. The author has not been able to verify the figures given; but the financial results based on the stated yields should encourage further investigation, especially if the respective sponsors will guarantee their results. If any or all are ready with a genuine business proposition, they will find the gas industry willing to give the matter serious consideration. The industry already possesses to a great extent the market for the solid fuel, and provides the only substantial outlet for the resultant gas. The local

market both for coke and gas is essential to the success of the system; and though the large plants erected in thickly-populated districts near the coalfield form a valuable and substantial first step, the solution of the problem nationally lies in the scattered gas-works, where the dual demand is already developed.

The three processes referred to are:

(1) The Maclaurin plant, which gives a typical low-temperature gas diluted with a larger volume of water gas (formed from the steam admitted to cool the coke) and producer gas (formed by the admission of air saturated with water vapour), the latter supplying the heat of carbonization.

(2) The Nielsen plant, consisting of complete gasification in conjunction with low temperature, by means of which raw coal is used to improve the value of blue water gas (made from the solid residue of one stage in the process), by a double distillation. The process is, therefore, in three stages, which the inventor considers as the latest development for using his plant for the purpose of town gas supply. It is of interest to note that Mr. Nielsen considers that, to be financially sound, the capital cost should not exceed 10s. to 12s. per ton of coal distilled per annum, working 365 days a year, and that the working costs, including labour, fuel for carbonizing, repairs, and depreciation, must not exceed 4s. per ton.

(3) The "Coalite" plant, which is low-temperature carbonization pure and simple in a single stage, presumably distilled by producer gas, or at any rate by a fuel produced outside, keeping all the solid residue for the outside market.

A fourth process is the Marshall-Easton system, which consists of a water gas generator coupled with twin vertical retorts. The special feature of the twin vertical retort is that in each retort there is a hollow shaft and a twin screw or helix mounted on each shaft. These screws revolve at a predetermined rate, with the result that the coal is lowered through the retorts at a fixed rate, and the layer of coal is never more than 4½ in. thick. Any desired percentage of the low-temperature coke can be used in the water-gas producer. The potential sensible heat of the blow gases is used for carbonizing the coal at low temperature, and waste-heat boilers are incorporated for steam raising. The blue water gas made is passed through the coal during the process of carbonizing.

It would appear that, unless a substantial proportion of the coke is gasified in a generator, there would not be sufficient heat for carbonization of the coal, without outside assistance.

The following table shows the results given, and the financial return, when taking coal at 32s. per ton, the solid fuel at 35s. per ton, oils at 5d. per gallon after deducting the recovery costs, and sulphate at £4 13s. 4d. per ton profit. The capital is calculated from the only figures available on a basis of 240 maximum days per year; and the author has made certain adjustments, in order to draw a comparison between the four systems and the gas-works method, where usually the "coke for sale" is after providing fuel for distillation, as well as works boilers, &c. It is difficult to get exact comparisons, as the coals treated are not the same in all cases.

—	Maclaurin.	Nielsen.	Parker (Coalite).	Marshall-Easton.
Capital cost per ton of coal per annum	34s.	19s. 6d.	37s.	18s.
Do. per therm per annum	5·96d.	2·48d.	11·21d.	3·21d.
Gas per ton	27,400 ×	22,250 ×	5,600 ×	15,320 ×
	250	425	705	460
Therms per ton	68·5	94·5	39·6	71·5
Net coal cost per therm.	1·42d.	1·61d.	1·41d.	1·27d.
Labour and supervision per therm	0·27d.	about 0·25d.	..	0·25d.
Repairs per therm	0·36d.	about 0·30d.	..	0·25d.

(8).—OPERATING COSTS.

Under this heading are included wages, fuel or power costs, and repairs. All are important; and it is possible for an increase in wages to counterbalance a saving in net coals when comparing two systems, and frequently a particular plant may be chosen on account of low wages and repairs together.

Wages.—Dealing with wages first, it is difficult to lay down any hard and fast rule, as the scale of operation differs in almost every case, and the cost is dependent on the full or partial employment of the plant. Minor variations in the value of coal gas cannot be said to influence the wages costs per therm. Generally speaking, it may be accepted that the expenditure in wages is more a function of the amount of coal handled and the number of charges, than of the thermal yield. In machine charging, the number of charges is of more importance than the weight of the charge. At the same time, certain general rules regarding wages can be followed respecting the type of carbonizing, among which are the following.

(*a*) Vertical retorts are cheaper to operate per therm than horizontals.

(*b*) The additional therms obtained from steaming are gained at less cost per therm than the straight coal gas, thus reducing the cost of the whole; and this would apply even with steam generated in an outside plant.

(*c*) Water gas is cheaper (even per therm) than coal gas of the same size output, if each plant is operated to the same proportion of its maximum production.

(*d*) The additional therms obtained by carburetting are obtained for practically no increase in wages, thus reducing the overall wages cost per therm.

(*e*) Wages in complete gasification systems should be the lowest of all, if the plant is properly designed and in proper working order.

(*f*) A decrease in the carbonizing period for horizontal retorts will lead to increased wages per therm, unless there is sufficient elasticity in the arrangement of shifts, or the increase in therms per retort compensates for the more frequent charging.

(*g*) As a general rule, the less the amount of solid fuel handled per therm, the lower should be the expenditure on wages.

Consider for a moment the last of these rules in relation to the manufacture of gas in horizontal retorts and complete gasification, and examine the amount of solid fuel handled per 100 therms.

Horizontal Retorts—

To retorts (coal)	20 cwt.	
From retorts to producers (coke)	2¾ ,,	
From retorts to dump (coke and breeze)	11¼ ,,	
	34 cwt.	
For 70 therms—*i.e.*, for 100 therms	48·6 cwt.	(1)
Resultant coke gasified (assuming the above handling of coke suffices to deliver it to the water-gas plant).		
Additional fuel to boiler, say	1½ cwt.	
carbonizing in the plant the remaining 9¾ cwt.		
Total	35½ cwt.	
Therms in resultant water gas = 24,000 c.ft. × 300 = 72.		
Total, 142 from 1 ton of coal originally—*i.e.*, per 100 therms	25·0 cwt.	(2)
If second handling required for water-gas coke	31·9 cwt.	(3)
Complete Gasification (One Stage)—		
To plant	20 cwt.	
To boilers	3¼ ,,	
For 180 therms	23¼ cwt.	
i.e., for 100 therms.	12·9 cwt.	(4)

It is clear, therefore, that double-stage complete gasification is certain to result in lower wages per therm than horizontal retorts alone, and that complete gasification in one stage must be less than either. The above proportion would not hold good, but the difference should be substantial.

It is difficult to get actual wages comparisons, owing to the different methods of allocation in existence. Taking "Field's Analysis" for 1924, the lowest is 0·274d. per therm for Leicester, and the highest 0·875d. per therm for Bradford. It is probable that items are omitted in Leicester which are included in Bradford.

With regard to the comparative costs of wages for coal gas and carburetted water gas, in the same publication the figure for water gas amounts to 0·45d. per therm, and coal gas amounts to 0·55d. per therm or thereabouts.

The following are recently published figures for carboniz-

ing wages per therm made, though they may not all be compiled on the same basis :

	d.
Verticals at Glasgow	0·38
Verticals at Glasgow	0·39
Verticals at Coventry	0·27
Horizontals at Coventry	0·41
Tully gas at Halifax	0·55
Horizontals at South Metropolitan, 1924	0·52
Horizontals at Newcastle	0·40
Robinson's plant at Harrogate	0·20
Horizontals at Harrogate	0·40
Low Temperature (Maclaurin's estimate)	0·27
Eastbourne, horizontals—machine-charged	0·58
Welwyn, hand-charged retorts	0·99
Pinner, hand-charged retorts	0 90
Pinner, water gas lightly carburetted	0 75

The above figures are comparable when dealing with the same works, but, as before mentioned, the expenditure in the printed accounts conveys no evidence that one method of carbonizing or one quality of gas offers overwhelming advantages in wages expenditure.

In the case of water gas, the wages per therm decrease as the amount of carburetting increases; further, the wages increase as the plant is used at a lower percentage of its maximum.

In machine charging, the therms made per charge are of primary importance. Hence the reduction in wages which can be effected by changing from 8 to 12 hour charges while retaining 8-hour shifts. It often happens, however, that the throughput is slightly reduced by this change; but in considering wages only, the reduced number of charges should result in a saving.

Another objection to the 4-hour break between shifts is the difficulty in regulating the quality and the additional work put on parts of the plant during the concentrated period of rapid gas production. With regard to all the overhead charges such as salaries, collection, and management and administration, the costs under these headings would not be affected by the grade of gas. The number of therms sold is for all practical purposes independent of the grade; and no change can affect the costs per therm, unless the calorific value were put so high or so low as to cause numerous complaints, which would result in additional clerical work and greatly increased inspection charges. There is as much danger in going too high as too low; but the responsible official is not likely, except in emergencies, to go to such extremes as would bring trouble of this nature.

Repairs.—In considering repairs, the term must be used in the widest sense—*i.e.*, the estimate must be based on the total provision which is to be allowed for maintenance, repair, and ultimate renewal of the plant in either its original form or replacement in a modern form.

Taking meters as a simple example, the maintenance pure and simple may be very small, and independent of the grade or quality; but the repair of leathers would certainly be more with a low-grade gas devoid of oily matter or with an excess of oxygen. The life would also be distinctly less, with the result that the effect on the costs would not be immediately apparent. In a very few years the repair and maintenance would mount up in the case of the lower grade, and in (say) 10 to 15 years the effect of the shortened life would result in an abnormal expenditure in replacements.

In making comparisons between different works and different systems we are again faced with the lack of a standard method of cost allocation. In works "A" certain men are allocated to wages; in works "B" the same class might be allocated to maintenance, making the wages for "A" appear high and the repairs for "B" correspondingly high. Further, one undertaking debits to residuals what another would debit to maintenance. This difference extends also to the materials and standing charges such as inspection and supervision.

An examination of the repair and maintenance costs of many undertakings will show that approximately one-half of the total is expenditure on wages paid to the employees of the undertaking in question; and there are certain items which would be independent of the quality of the gas manufactured, so that the cost per therm would simply be a fixed annual charge divided by the number of therms sold.

With regard to the maintenance, repairs, and renewals of the exhausters, washing plant, purifiers, and gasholders, it is clear that a low grade of gas would necessitate a larger piece of plant in each case; and consequently the fuel, oil, paint, and general attention would be more than in the case of a higher grade, and the cost of repairs and renewals would be higher. Consequently the higher the quality the lower the repairs and maintenance costs would be.

The estimates for the corresponding expenses for the carbonizing plant and coal and coke handling machinery are not such simple matters, however, though considerable assistance is given by the experience of the past, and certain basic considerations. For instance, for coal handling, the cheapest plant per therm would be that handling the least coal, and therefore the system producing the lowest cost in respect of this item would be that producing the maximum number of therms per ton. The same would apply to the coke plant. In both, however, certain fixed charges must be met, and the time element must be a factor, as a plant handling no coal or coke would require a certain amount of maintenance. Further, a large plant on a reduced tonnage would not show the same saving as a new plant of smaller size.

In the case of charging machinery, there are certain maintenance charges which are fixed amounts, and other variable charges dependent on the type of machine, and speed and amount of coal dealt with; but probably the heaviest part is that caused by the wear of the chain and portions which are put into the retort. Consequently the lowest cost of upkeep is that which entails the minimum number of charges put in the retorts for each 100 therms manufactured.

With regard to the retorts proper, higher heats entail higher repair charges; but the additional therms obtained by increased throughput and higher thermal make per ton may well compensate for this. The throughput of coal is dependent substantially on combustion-chamber temperatures; and in conjunction with this one must consider whether the charge can be adequately burnt-off in less time than that actually employed. In other words, high thermal yield cannot always be maintained in addition to high throughput. A more important factor in retort repairs, however, is the variation in the heat of the retort caused by the introduction of cold coal, coupled with the damage due to the insertion of the chain and pusher head. Consequently the least expensive method for each retort is that which gives the greatest number of therms per charge

In comparing types of carbonizing plant, the repairs of the simpler types of plant will obviously be less than those more complicated. Therefore the repairs to a water-gas plant or a complete gasification plant should be lower per therm than other systems, for two reasons :

(1) Less costly on account of the actual material in them.

(2) More therms produced per ton of coal or coke.

The size of the unit is of importance, for it is costly to throw-out a unit forming a substantial proportion of the daily make for a repair in a limited part of the setting. This causes wear and tear on the spare plant put into operation, and the expenditure on the actual repair is higher than it need be per therm of gas made. For instance, supposing a defect in a bed of horizontals necessitated resetting from charging-floor level. If a bed of ten throughs were involved, this might cost £450, whereas if the economic unit of the works is more like six retorts, the corresponding repair would only be £275, or thereabouts.

Capital costs are dealt with later, but the first cost has a bearing on the charge necessary for complete reconstruction or replacement due to obsolescence.

The effect of the annual charge for sinking fund based on a useful life of (say) 35 years would not be important when divided over the gas made annually. The difference between the cheapest and the dearest plant would not be likely to exceed 0·05d. per therm manufactured.

In dealing with existing plants, the rival claims of thermal make per ton, per retort per day, and per charge have to be considered. The following table is based on a make of 10,000 therms per day, with 23 in. by 16 in. retorts 20 ft. long, or (say) 18 ft. run effectively charged. The tons of coal used may be said fairly to represent the "net coal factor," the retorts at work the "capital factor." and the retorts charged per day the "wages factor." The "repair factor" would be a combination of retorts charged per day and retorts at work.

With a fixed combustion-chamber temperature, the distillation temperature would be higher when less coal is being carbonized in the retort; and consequently it is more

The table is based on 10 cwt. for 8-hour charges, 12 cwt. for 10-hour charges, and 13⅓ cwt. for 12-hour charges.

difficult to get the increased yield per ton from heavy charges without extending the time of carbonization. The ideal is to strike the balance by arriving at the quantity best carbonized in a given period, without losing throughput and burning fuel in an endeavour to knock out a further therm or so per ton. There is a danger of therms per ton becoming a fetish, as in pre-war days "high makes" per ton were deemed a virtue without any other consideration. If the high yield per ton could be got in eight hours, the repair costs of operating 93 retorts with 279 charges per day must be balanced against 101 retorts (say one more bed) with only 202 openings per day. The total differences, however, would be small and less important than those due to differences in the design of plant or the quality of materials and workmanship in the setting.

It has been claimed that deliberately lowering the throughput enables emergencies to be met, but it is doubtful whether it would not be preferable to adhere to the most economical retort-house working, and take up emergencies with auxiliary plant. In verticals, of course, steaming is of emergency value; and it is possible to increase the percentage of steam, and compensate for the lower calorific value, by using more oil in the water-gas plant. If there is no water-gas plant, then extra steaming does not offer any substantial attraction in this respect.

With regard to mains and services, it has been shown earlier that either larger mains must be used with a lower calorific value, or, alternatively, increased initial pressures. The capital costs of mains or operating costs of boosting must be taken into account; but only the repairs are for the moment under consideration. There is little doubt that the low grade causes increased running costs for maintenance and renewal of services; and the chief expense would arise in relaying services in a larger diameter, and replacing all services on the district on a larger scale when the first replacement is complete. The same would apply to mains. Therefore, even if the distribution system is capable of dealing with the lower quality, the system loses a potential margin for increase which it would possess if the calorific value were kept at a higher figure. There is no doubt, therefore, that the district repairs, as well as the over-all distribution costs, would be higher with low-grade gas.

With regard to the repair of meters, it will be admitted that any given size of meter is capable of registration of more therms with a high-grade gas than with a low. Consequently, if a substantial drop in calorific value were to take place, it might be necessary to enlarge some meters on the district, with a consequent increase in maintenance per therm sold. Reference has already been made to the increased costs of maintenance due to low-grade gases produced by "stripping" and other methods of manufacture.

At the same time, in many houses the meter maintenance is probably a fixed item, in which the time element is the principal factor; and, therefore, the cost of repair as a total would be independent of the calorific value, if kept within reasonable limits.

The best way to reduce meter repairs is to increase the annual consumption.

It is of interest to examine the probable maximum hourly consumption per consumer during the year; and the following table is compiled from information furnished by the engineers of the various undertakings concerned.

The figures of consumption per hour appear very low, and the table shows the further scope for increase in gas consumption in any type of town; and it seems to prove that a very large proportion of the meters on a district are of ample size. The great difference between the figures for similar industrial towns like Birmingham and Leeds is worthy of note.

Table of Maximum Day and Maximum Hour.

—	Max. Day. Thousands C.Ft.	Proportion of Yearly Send-out.	Maximum Hour. Thousands C.Ft.	Factor Day / Max. Hr.	C.Ft. per Consumer per Max Hr.	Therms per Consumer per Max. Hr.

Widnes	1,822	1/355	125	14·4	14·5	·072

Note.—The factor $\frac{\text{Day}}{\text{Max. Hr.}}$ relates to the day's send-out in which the maximum hour occurs.

In cases where the maximum hour does not occur on the maximum day, the send-out in the day comprising the maximum hour is shown in brackets.

An interesting note on the subject of maximum hourly consumption is given in the case of two undertakings of residential character. The maximum hour is no longer the Sunday cooking load, but (in the first case) the breakfast hours of a winter morning, caused by the combination of lighting, gas-fires, and cooker hotplates. In the second case it is on Monday morning, when the weekly wash is in progress.

To return to the subject of repairs, the repairs to cookers and fires would appear to be independent of the calorific value. The burning of gas involves the use of the cooker; and the cost of maintenance is dependent more on the type of appliance chosen and the treatment given it by the individual consumer. Inspection charges represent a proportion of the cost; and the care given to the original adjustment, coupled with the consistency of pressure and composition, is of more importance than the choice of the calorific value. Other things being equal, the repair cost is a function of time and gas consumed.

Therefore, the position under the thermal (as compared with the volume) basis is unchanged; and, as a rough rule, the more the appliance is used, the less is the upkeep per therm.

(9).—Capital Costs and Rate of Interest on Money.

This factor is of great importance when new plant is under consideration, as money is usually dear at the time the required plant is most expensive. The thermal output must be considered in conjunction with the annual interest and sinking fund (or interest and depreciation) charges based on the estimated useful life of the plant; and in making the choice the necessary expenditure to other parts of the plant (if any) must be considered.

Simplicity of design is of importance; and the plant should be capable of renewal in comparatively small sections, avoiding the renewal of substantial parts of the work, as the wear may be confined to small portions. The

size of the unit must be considered, as a section used at a small proportion of its output is costly. The capital and sinking fund charges should therefore be assessed on the estimated requirements, and not on the maximum capacity.

The following table gives approximate costs of a plant making 10,000 therms per day, including coal stores, coke and coal handling plant, generating plant, and preliminary condensation. The useful life is taken at 33 years (1 p.ct. sinking fund on 6 p.ct. basis), and the interest at 6 p.ct. If the nature of the plant necessitates a shorter working life, then the sinking fund must be adjusted accordingly.

The annual make is taken at 240 maximum days = 2,400,000 therms.

Type of Plant.	Cost.	Interest and S.F. per Annum at 7 P.Ct.	Interest and S.F. per Therm Made
	£	£	d.
Horizontal retorts.	40,000	2800	0·28
Vertical retorts	50,000	3500	0·35
Carburetted water-gas plant . .	26,000	1820	0·18
Tully plant.	30,500	2135	0·21
Robinson plant	42,500	2977	0·30
Parker low temperature	112,000	7840	0·78
Maclaurin ,, ,, ...	60,000	4200	0·42
Nielsen ,, ,, ...	25,000	1750	0·175
Marshall-Easton ,, ...	33,000	2310	0·23

From the above figures it is clear that the lower-grade gas is considerably cheaper with respect to capital; and this is to be expected where the process consists in the more or less complete gasification of the fuel. In addition to occasions when new plant is required, a change of calorific value may involve capital expenditure, or alternatively result in postponing it. Owing to the trend of markets, a lower calorific value may result in a great saving in manufacturing costs, but entail heavy capital expenditure in mains, services, boosting plant, or even storage plant. Therefore, the economic effect of this expenditure must be balanced against the savings. If the relative values of coal and residuals appeared to be stabilized at such a ratio that low-grade gas would be cheaper over a long period, then it is probable that the savings would not be swallowed-up by distribution expenditure; and if in the future the balance should be affected, then the money so expended would probably be fruitful in taking up increased business. Each case must be considered on its merits.

Coal Conservation.

It has frequently been asserted that coal is conserved to a greater extent by carbonizing systems producing a large number of therms per ton of coal, but the figures and conclusions drawn therefrom usually ignore the utilization of the solid fuel distributed. Consider two processes:

(*a*) One ton of coal gasified by producing 70 therms of gas and 10½ cwt. of coke and breeze for sale.

(*b*) One ton of coal gasified completely by producing 175 therms of gas; this process requiring also 3¼ cwt. of coke.

In process (*a*) the gas undertaking must carbonize 2½ tons of coal to manufacture 175 therms; but this amount of coal releases 26¼ cwt. of coke, or 29½ cwt. of coke more than process (*b*). By withdrawing this quantity of coke, the market would need solid fuel (coal) to the extent of at least 25 cwt.; so that process (*b*) requires 20 cwt. *plus* 25 cwt. = 45 cwt. before satisfying equal requirements, against 50 cwt. for process (*a*). The difference is therefore very slight. In many industrial applications the amount of coal would be at least equal to coke, so that the above figures do not overstate the case. If the withdrawal of solid fuel under process (*a*) resulted in an increased sale of gas giving greater efficiency than solid fuel, then the figures would be more favourable to process (*b*); but this cannot be guaranteed.

Wastage.

Wastage is of two kinds:

(1) That caused by incorrect adjustment of the appliances.

(2) That caused by the householder.

With regard to (1), there is little doubt that a very high calorific value is liable to lead to more wastage than a very low grade; and, of course, the consumer has no control, or at best only a partial control, over this form of loss.

With regard to (2) this falls under three main headings:

(*a*) Burners lighted unnecessarily.

(*b*) Burners kept on after the work is done, such as a boiling ring left on after the kettle has boiled.

(*c*) Taps turned on too full, causing the flame to reach round the sides of the vessel, or resulting in inefficient lighting of a mantle.

Wastage under (*a*) is merely a function of time, and is independent of the calorific value, as the thermal units per minute reaching the burner should vary only within narrow limits. The same applies to (*b*), for it cannot be conceived that the wasteful user will leave the burners on longer than is necessary with a high grade any more than with a low grade. With regard to (*c*), it is probable that more wastage will occur with a high grade, particularly in lighting; and this can only be cured by repeated advice and education.

With reference to leakage, it is probably unaffected by the grade. Low grade requires higher pressures; but a certain sized orifice would deliver no more thermal units in a certain time, as the increased volume lost due to higher pressures would contain less heat units per cubic foot. The unaccounted-for gas due to difference of temperature between the station meter and the consumer's meters is unaffected by the grade. The unaccounted-for gas due to loss in registration by defective leathers and mechanism is likely to be increased by low-grade gases, though it is difficult to estimate the effect in figures.

On the balance, therefore, keeping to a high grade will not increase the leakage and unaccounted-for, but a lowering of the value might have that effect.

Discussion.

The PRESIDENT: You will agree with me when I say that Mr. Evetts has given us a most able paper and a most comprehensive one, on which he must have spent an enormous amount of time gathering together the information he has presented to us in tabulated form, which will be of the greatest value to the Institution. I am glad to find so many here to listen to this paper; and though we have not much time to discuss it, I know there are several gentlemen here who would like to take part in the discussion. Mr. Marshall's name has been mentioned in connection with one or two processes, and I will ask him to open the discussion.

Mr. MARSHALL: We have had the privilege of listening to a most interesting paper, and I personally wish to tender my thanks to the author. As my process has been mentioned, and as the whole subject of carbonization, whether at high or low temperatures, is connected with the thermal basis, perhaps I may be permitted to criticize or traverse some of the statements made—not because there is any disagreement between us, but for the reason that the paper was in print before I had the pleasure of meeting Mr. Evetts and having a talk with him over the matter. This question of low-temperature carbonization has been exercising our minds for a great many years. I personally have been nine years at the work. I have put down a works at Battersea, and through this plant I have put 2000 tons of coal, representing samples from every quarter of the globe, and I suppose I have been able to tabulate, with Mr. Tozer, results which have never been tabulated before, as far as the yields of gas and oil are concerned. What we have been striving for is not alone to get a smokeless fuel, but to get an oil which would render us quite independent of the American imported oil or oil from any other part of the world. We have been successful in obtaining oils which are equivalent to the best American oil imported into this country, and from our oils we have been able to extract a petrol with which we have driven a motor-car 300 to 400 miles with results equal to the best petrol in the world. All this can be got easily from some of our best gas coals. The question is whether low-temperature carbonization can pay. My view is that it cannot as an entity. If it is to stand alone outside the gas-works, there is no commercial prospect for it at all; but if you can use the low-temperature process in combination with a gas-works, then there is a very great future, in my humble opinion, for low-temperature carbonization. First of all I might say that I have had charge of many high-temperature works, but honestly I have always felt that we were wrong. I have not, however, been in a position to prove it, or say very much about it hitherto, or do much to mend matters. As an individual, I felt that we were going beyond the limits of economy in pressing our retorts to 2200° Fahr., and I do not think any of us know what the last 3000 c.ft. of gas per ton costs in reality. I have often discussed the matter with my brother-in-law, Mr. Goulden, of the Gas Light and Coke Company, and he has sometimes agreed with me that we have got to the limit of

economy in high-temperature carbonization. But coming back to low-temperature carbonization, what I am proposing to do, and have done, is this. The retorts I have put up hitherto have been static retorts—*i.e.*, to charge at the top and discharge at the bottom, at intervals of four hours. Each retort contains 5 tons. There are three rings of holes one above the other, and the heat is taken from the periphery to the inner rings. I have a working plant at the present time in operation in Natal, and there is another one being erected in Japan; but I feel that this is not finality. We can work it very well with Natal labour and with Japanese labour, but such a plant would be absolutely impossible if we tried to work it with British labour. Therefore I had to start all over again. Some years ago I lectured at Manchester before the Manchester Association of Engineers, and I told them plainly that I saw through a glass darkly as to how far low-temperature carbonization would help the gas industry; and for some years after that the glass was always obscured. It was only through working the Tully plant that I arrived at some definite means which cleared my thoughts. Whatever we think of the merits and demerits, we must agree that we owe Mr. C. B. Tully an immense debt of gratitude for what he did; and though I have had disputes with Mr. Tully, I look upon him as one of the pioneers in a line of thought which, if followed up, will help us very much in the future. What I wanted to get at was to make the retort continuous. I did not care what type of coal was used, whether it was the stickiest coal in the world. If I could induce that coal to travel, I knew it would be all right. Therefore, I set to work to design a plant, and I have erected it in my own garden. I have got coal from the Walton and Weybridge Gas Company, which is the stickiest stuff I have ever handled, and a piece the size of an egg will swell to the size of a coconut. I have been able to compress that into a solid coke containing from 10 to 15 p.ct. of volatile matter, and I have been able to get that coal absolutely down the retort without the slightest trouble. Moreover, I have been able to get 24 gallons of oil, which is some of the most remarkable oil I have ever seen. I have brought a small bottle of it with me. It is so volatile and so inflammable that, if you put a knife into it and strike a match, it will flame up like petrol. I have 24 gallons of that from this little retort. The great thing is what we can do with low-temperature retorts. If we have to heat them with the coke we produce, it cannot possibly pay, because we must take account of the cost of that coke. Following Mr. Tully's idea, which has been carried on by Prof. Stauffe, of Vienna, if we can get heat from an extraneous source without paying for it, then we will possibly be able to carbonize cheaply. If we have a water gas plant, we shall have more heat than we require to carry out low-temperature carbonization. It means that the low-temperature retort will give the fuel for the water gas plant, which in turn will give waste heat back to the low-temperature plant. Mr. Evetts has raised the question of what proportion of coke we must take to carry out low-temperature carbonization. In high-temperature work we used 26 therms of heat to carbonize one ton of coal—*i.e.*, we use about 2,600,000 B.Th.U., representing 10 p.ct. of coke, to heat a high-temperature retort. If we take a low-temperature retort, we only want half that amount, or 1,300,000 B.Th.U., to heat the retort, if I use the whole of the coke, but I do not want to. I can use a quarter of that coke, and still get sufficient heat to do what I want. If I use a quarter of the coke, which is equal to 46 therms, and deduct from this the heat required for steam raising and running the turbine, and the coke used in the process of water gas making, I get supplied to the generator 11 therms; and 11 therms is almost half of 26 therms which I should want if I were operating a high-temperature plant. If I take all the coke, I get 15 cwt. from the low-temperature carbonization process, and this coke contains 10 p.ct. of volatile matter. I then deduct 18 p.ct. for steam-raising purposes, which leaves me a net amount of coke of 12·3 cwt. If I use all this coke, which is 1377·6 lbs., and take 30 c.ft. of water gas per lb., I get 41,310 c.ft. of water gas of 306 B.Th.U. value. Then from the low-temperature retort I get a fixed quantity of 5000 c.ft. per ton, of rich coal gas of 800 B.Th.U.—that is, 4,000,000 B.Th.U., or 40 therms. If you can do this—as I say you can—and you add those 40 therms to the other therms, then you are doing very well indeed. The result therefore is 41,310 c.ft. of water gas, which gives me 126 therms, and 5000 c.ft. of rich coal gas, which gives 40 therms, or a total of 166 therms per ton of coal, but I have no coke to sell. In addition, however, I have 24 to 30 gallons of oil per ton. The question of the value of this oil depends upon the volatile matter in it. In my experience of thousands of gallons I have found that for every 1 p.ct. of volatile in the coal, you obtain from $\frac{1}{2}$ to $\frac{3}{4}$ gallon of crude oil which will fractionate into petrol, light oil, heavy oil, lubricating oil, paraffin wax, and pitch; and the pitch is the most remarkable thing. It contains only $3\frac{1}{2}$ p.ct. of carbon. If I use half the coke, I get 20,640 c.ft. of water gas, to which has to be added 5000 c.ft. of rich coal gas, this quantity being fixed, whatever proportion of coke I use. Thus I get 25,000 c.ft. of gas in all, or 103 therms per ton of coal. If I take a quarter of the coke, I get 15,000 c.ft. of mixed gas, or a total of 71 therms per ton, and I get 9 cwt. of coke for sale in the latter case, or 6 cwt. if I use half the coke. The process is so elastic that you can get gas of from 306 to 500 B.Th.U. by regulating the supply of coke put into the generator.

DR. E. W. SMITH: One feels very tempted to follow up Mr. Marshall on this question of low-temperature carbonization; but as it is not to the point, I do not think I will say more than that the scheme which Mr. Marshall propounds—one in which the low-temperature carbonization process is to be wedded to a gas-works, and one in which the waste heat normally used for raising steam is to be used for heating the retorts—is not one which is attractive to the gas industry. Then there is another point. If such a process has no attraction to anybody outside the gas industry, we shall want a lot of convincing as to why the gas industry should carry the baby. If it is really of value as a low-temperature process—and Mr. Marshall is satisfied that low temperature is now an assured success—the gas industry will also want to be assured of success if it takes it up. There are one or two points in connection with the paper to which I should like to refer; and I think this is the type of paper that should be more general. I think Mr. Evetts would like to have accentuated that he does not desire to indicate more than tendencies in methods of looking at things. I think he makes that point time after time in a guarded way. These tables in the paper must not be taken as standard tables for comparison; they must be taken as being indicative of how to work out your own results for your own comparisons. I should like to ask Mr. Evetts whether there is a misprint where he gives verticals, light steaming, as 57 therms per ton. I think it would be very bad coal and very bad verticals if anything less than 70 therms per ton were obtained under these conditions. I think it is probably a misprint, but it just shows you how important it is when engineers and first-class accountants get together, to get down to relative values of different systems, that the primary thing is for the facts to be right, because a small discrepancy like that may vitiate the whole of the results. I do not say it is so in this case; but it is a point to be met. There is another point I should like to ask the author, though perhaps he has not gone into the matter in sufficient detail to be able to answer at once; and that is to have an evaluation in greater detail of the relative advantages of the two recommendations he makes. He advocates high-grade gas because of distribution, but he does not give us enough leading as to the comparison between the cost of distribution generally and in detail, and the cost of production and management. Then, later on, he strongly advocates, for other reasons, 360 B.Th.U. gas. He does not give this figure, but he supports complete gasification. Now, can he put these two things together, and say, from the point of view of the distribution of 500 B.Th.U. gas, that it will pay handsomely, and from the point of view of the production of 360 B.Th.U. gas, that pays handsomely.

MR. F. H. ROBINSON (Harrogate): Mr. Evetts states that as a general rule water gas does not pay if 55 p.ct. or more of the cost of the coal is obtained from residuals. At Harrogate last year, with a complete gasification plant, with the price of coal at 27s. per ton, I estimated that the cost of complete gasification would equal the cost of straight coal gas making when the price of coke was 10s. or 11s. per ton higher, and that means that, with coal at 27s. per ton, coke would be from 37s. to 38s. per ton for the cost to be equal on the two systems. When I state this, I am basing it on a complete balance-sheet, and not upon thermal efficiencies or anything of that kind—*i.e.*, to take so much plant of the one type and so much plant of the other kind, and bring the figures together, and see what labour would be required to work the two plants in conjunction, and add for repairs, and strike a complete balance to produce a certain cost. If you do not take a complete balance-sheet, I say that the figures are misleading in every case. If we take materials alone, ignoring other factors, we should have required a difference in the coke price of 15s. or 16s. a ton to bring the two costs the same. While on the question of cost, and the cost per therm, I feel it is too often the case that cost is the only thing considered, and that the poor consumer is left out of account, for the reason that, when coke is cheap and coal is relatively dear, the policy seems to be water gas, and you reverse the policy when the conditions are the opposite. But what is the consumer to do in the meantime? On the one hand, you are going to give him a gas of a certain composition, perhaps with 10 or 15 p.ct. of CO, while with straight coal gas you have about 7 p.ct. of CO, and the quality, composition, and specific gravity are completely altered, and all the apparatus of the consumer is thrown out of order. I think the policy should be to reduce the amount of coal you carbonize, and reduce the amount of coke you produce, and make yourselves more independent of the fluctuations in these markets; and by that means you will attain greater stability. That has been seen recently, particularly on the north-east coast. I have in mind a certain works where they have several thousand tons of coke on the works, which are the same size as my own, and where the policy in the past has been to make straight coal gas with large quantities of coke for export. But they are in a pickle

at the present time, owing to the state of the coke market; and if there had been some policy followed of the kind I have indicated, they would have been in a different position to-day. Mr. Evetts makes a statement with regard to the repair and wages costs on complete gasification plants; and after stating the figures for Harrogate, he adds "presumably on the same basis." That is so; the figures include everything from the time the coal leaves the coal seller to the time the final materials are put into the yard in the shape of coke and ashes. As to the value of two shifts per day *versus* three, we have worked in this way for the past nine years; and from our point of view there are several advantages. You have less repairs and maintenance; you have a reserve machine; you have a reserve for an unexpectedly heavy demand; and you have a reserve in plant capacity for future extensions. With regard to the table dealing with the consumption per consumer per maximum day and maximum hour, I rather join issue with the author, because I feel that this table may be misleading. The factor $\frac{\text{day}}{\text{max. hour}}$, to be ideal, would obviously have to be 24 hours; and taking Cardiff and Leeds, the former has a factor of 5·1 with a consumption per consumer of 18·3 c.ft. In the case of Leeds the figures are practically reversed, and it seems to me that Leeds is in the happier position, because their maximum consumption is spread over a greater number of hours. I should like to thank Mr. Evetts for a very thorough paper; and I feel that it should be read in conjunction with Mr. Carr's paper.

Mr. S. Shadbolt (South Bank): I think we must bear in mind that this paper is largely a collation of facts and figures from other people's working, and a reasoned consideration and statement of the case as Mr. Evetts views it. I speak as one on the other side, who, barring the slight stagger inflicted upon us by the coal strike of 1921, has for three complete financial years supplied a 400 B.Th.U. (gross) gas in my district, with very little variation and with a constant effort to stabilize, as near as one can, an ideal composition, and also with a close guard against unduly increasing the specific gravity. I have therefore made a few notes from that point of view. The author expresses the opinion early in the paper that thermal consumption will probably remain unaltered by varying the calorific standard. I am able to assure him, from actual observation of my own consumers, that, in the case of power consumers, you can almost work it out mathematically. You can get the volume which a man will burn on a steady load, just by simple proportion; but it is not nearly so reliable when you come to domestic consumption. Further on in the paper the author voices the opinion that I have uttered myself on more than one occasion—that there is considerable risk of wastage with the higher qualities of gas which is not there with the lower qualities. The author states: "Reducing the value might cause difficulties, but increasing it should not." My experience is that there should be no "messing about" with the value at all, because there are bound to be some difficulties. Then the question of high-grade gas and pressure is mentioned; and the author states that less pressure is required to deliver thermal units in a highly condensed form, due to the less volume to be dealt with; but for bunsen burner work you require more pressure to aerate your flame on the jet, because you want a bigger proportion of air. We have come across this in actual use. Finally, the author refers to wastage. He states that a certain size orifice will deliver no more thermal units in a certain time, as the increased volume lost due to higher pressures would contain less heat units per cubic foot. I am afraid he takes for granted a very finely balanced adjustment of pressures, which will never materialize in actual fact, and ignores the experience which many of us have met with—that with increased pressures you run the risk of sudden fractures. Both factors make any leak more serious, though, of course, they lead to a more rapid diagnosis and elimination of leakages. I have found in practice in my own area that an increase in pressure has been of assistance in keeping down the unaccounted-for gas. This leads me to my last point, which deals with the unaccounted-for gas in my district. For the last fourteen years the average unaccounted-for gas has been 5·65 p.ct. At the beginning of that period we were supplying 550 B.Th.U. gas, and for the last three full years, barring the coal strike period, we have supplied 400 B.Th.U. gas. During the first year of the fourteen years the loss was 6¾ p.ct., while last year it was 6·05 p.ct., and the average is 5·65 p.ct. There is an absolute case from experience which shows that the volumetric unaccounted-for gas need not be increased by decreasing the calorific value from 550 to 400 B.Th.U.

Mr. Watson (Doncaster): Is this with the same make of gas?

Mr. Shadbolt: It is the percentage volumetric leakage from the whole of the output. The works, of course, has progressed in fourteen years, as, I hope, every works has, and the output now is about 150 millions as against 100 millions. Taking the actual calorific value now, and before the war, while the leakage remains volumetrically about the same, the thermal loss has been reduced exactly 27·27 p.ct., and I think it is time that this point was observed.

Mr. Morland (Sydney): It has given me very great pleasure to attend these meetings. Unfortunately I have not been able to be present as frequently as I should wish, but the papers to which we have listened this morning are undoubtedly excellent. In the Colonies, of course, we do what we can to keep our methods and practice up to date, and we follow, as far as we can, English practice, unless we are able to discover something better ourselves. However, judging from my experience during this trip home and also other trips, I think that we in the Colonies are up to date in our methods. We have not yet adopted the therm system, because Parliament, unfortunately, has not permitted us to do so; but I anticipate that some day we shall be able to adopt the therm system, and we shall benefit in doing so. We have all sorts of plant in use in the Australian States—horizontals, verticals, and complete gasification plants—and we are working out for ourselves, as far as we can, the relative advantages of the different systems. In my works we make our gas by inclines, verticals, and water gas plant.

The President: Mr. Evetts refers in several parts of the paper to high quality and low quality gas. Perhaps he will tell us what he means by high and low quality gas.

Mr. Evetts, replying to the discussion, said: I daresay you have tumbled to it by this time that the use of these terms is empirical. Anything over 500 B.Th.U. I call high quality, and anything under 400 B.Th.U. I call low-grade gas. Between these figures I have not any opinion as to whether it is high or low. With regard to Mr. Marshall's remarks, he has given us a very interesting series of figures as to what his plant could do, and I beg to assure him and every other maker of gas plant in this country that the Institution of Gas Engineers and the individual members, if they see a guaranteed proposition for making a cheap therm, do not care what this is made from, or what the plant is made of. They will look at it, and consider it, no matter whether it is high temperature, low temperature, or complete gasification. The method is immaterial to us; we want to make a therm cheaply. My objection to Mr. Marshall's method of attack (if I may say so—I have told him this in correspondence) is that I do not agree with him in taking a piece of everything, and then combining it in his plant, and saying: "That is what I can do." For instance, he gives 30 c.ft. per lb. of coke as the production of water gas of 360 B.Th.U. It may have been done, but how many of you are doing it to-day in your works as a practical proposition? Mr. Marshall says, further, that the heat from a quarter of the resultant coke in the low-temperature plant is going to provide sufficient heat to carbonize the coal. I cannot accept this proposition. He then calculates on 15 cwt. of coke or low-temperature fuel. This, again, is a result second to none. In other words, where can you find your coal to give you 15 cwt. of coke, the 20 or 24 gallons of oil, the 30 c.ft. of water gas of 366 B.Th.U. per lb. of coke, and the resultant heat from a quarter of the coke to gasify the coal? Dr. Smith has pointed out one or two things. The figure he mentioned in the table of net coal costs is a figure from the Fuel Research Board, and it so struck me that I draw attention to it. This coal was Lancashire washed nuts, and produced only 9670 c.ft. of 600 B.Th.U. gas, or 58 therms per ton, with 8·1 cwt. of coke for sale, when carbonized in horizontal retorts. Obviously it is not a good coal, and I put it in to show you that, by steaming it down to below 400, even with that inferior coal, you produce an extra 38 therms of gas at ¾d. per therm for the additional manufacture. Dr. Smith's comments on what I intended this paper to be are perfectly true. I wish each case to be considered on its merits; and in this paper I wanted to indicate lines of investigation for you to follow up for yourselves. He also asked me whether I can say, on balance, what is the right thing to do, whether the advantages of high-grade gas more than correspond, in distribution, to the advantage in the works of the manufacture of low-grade gas, and he supplied the answer himself. Of course, I cannot tell you. Each case has to be considered on its merits; and I would warn anybody against taking any short cuts with these things. The only thing, as has been pointed out, is to get a parallel balance-sheet for system A and system B, and run it to the bitter end. Do not stop half way, and say that A is the better. There must be no short cuts. The financial result has to be followed to the end with the various methods. Mr. Robinson has questioned my statement that as a general rule water gas does not pay if 55 p.ct. or more of the cost of coal can be obtained from the residuals. That relates to net coal only. This paper is divided into paragraphs, and only considers the points strictly arising within those paragraphs, and the 55 p.ct. refers to the net cost of coal, and is calculated by the usually accepted means of ascertaining the cost of coal, and the usually accepted balance of prices between coal and coke. Mr. Robinson also raised the point about ringing the changes on the calorific value owing to the trend of markets, and the difficulties likely to be caused to the consumers by changing the composition and specific gravity. I point out in the paper that we must consider if any change in the calorific value is likely to affect the satisfaction of the consumers. If it is, then do not make it, no matter what it would have saved you. I do not think I have lost that point

altogether. I am much obliged to Mr. Robinson for giving us the advantages of the 12-hour shift, but he must have a plant capable of dealing with 24 hours' gas, as it were, in comparatively quick rushes. Mr. Shadbolt has been good enough to give us the result of his experiences just on the margin of what I call low-grade gas, the 400 B.Th.U. He also asked me what I meant by saying that reducing the value might cause difficulties, but that increasing it should not. I have in mind there that in the case of three particular companies we have eliminated trouble with the consumers by going up from 475 to 500 B.Th.U. It may have been that it was the pressure which was the trouble at 475 B.Th.U., but the difference in the number of complaints was remarkable when we started to work towards the 500 B.Th.U. We first went up to 485, then to 490, and then to 495, all the while with a declared value of 475, and then we went up with our declaration when we were over 500 B.Th.U. In two cases out of the three the number of complaints began automatically to drop as we raised the value; and this was the reason for making the statement to which Mr. Shadbolt has referred. In my humble opinion you could increase it to 550 in most cases without causing dissatisfaction. Above 550 I have my doubts, particularly in my own house. Mr. Shadbolt also gave some interesting figures as to the way in which the leakage has been reduced. I do not think I put forward the suggestion that leakage was going to be made worse by low-grade gas. I simply said I would show how it could be made better. Mr. Shadbolt's figures are on a make 50 p.ct. greater; and one would except the leakage to be less with 150 millions than with 100 millions, particularly as probably in the meantime you have stiffened up your distribution department, and paid much greater attention to the consumers generally than you did fourteen years ago. In my opinion this fact alone should tend to reduce the amount of unaccounted-for gas.

The PRESIDENT: I should like to express, on your behalf, our gratification to Mr. Evetts for presenting this paper, on which he must have spent an enormous amount of time. I am certain that the opinion of the members will be that the last paper maintains fully the high level of the communications that have been received at our annual conference this year. I am sorry it was not possible to let the members have advance copies of some of the papers, but the Whitsuntide holiday was a week previous to the meeting, and I can assure you that everything was done to get copies into your hands as quickly as possible. The only thing I am afraid of is that, if we had let the members have the papers a week before, we should have had to have another session to-morrow instead of going to Derby. [Laughter.] I should like you to express your hearty appreciation of the paper, and to thank Mr. Evetts for it.

THE GAS INDUSTRY AND THE GOVERNMENT.

From the Ministry of Transport we have received the following announcement, dated June 9:

The Minister of Transport, who was accompanied by Sir Burton Chadwick, M.P., and Colonel Moore-Brabazon, M.P., received a deputation to-day, introduced by Mr. Milne Watson, representative of practically the whole of the company and municipal gas undertakings.

Mr. Milne Watson and other speakers indicated the uncertainty which prevailed in the industry at the present time, owing to their ignorance of the Government's proposals with regard to electrical development. The views of the gas industry were stated at some length by various speakers; and the Minister was asked to be good enough to indicate as soon as possible any proposals which the Government would consider might affect in any way the gas and the electrical industries.

Colonel Ashley, in reply, stated that it was impossible for him at present to indicate what any Government proposals might be; but he undertook to bear in mind the representations which had been made to him, and to see that due consideration was given to them. He would be glad at any time to receive representations from those interested.

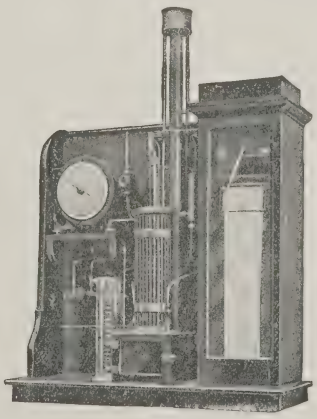
Gas and the Cinema Industry.—In the "Capitol" Cinema—perhaps the most beautiful and most perfectly-equipped cinema theatre in Europe—the air can be heated in the winter and cooled in the summer in order to make the temperature comfortable, and before it enters the theatre it is cleansed of all impurities. Fog cannot enter the building, owing to the air being under a pressure slightly higher than normal atmospheric pressure. The "Plenum" plant, which carries out the double operation of cleaning and heating the air, utilizes a large gas-fired boiler for providing the heat, and thus ensures that neither dirt nor smoke is created in the heating operation. Full particulars of this plant, the boilers of which are situated on the roof of the building, are contained in the current issue (No. 135) of "A Thousand-and-One Uses for Gas."

SIMMANCE'S

PATENT

TOTAL HEAT RECORDING CALORIMETER

The only Recording Calorimeter which combines a Standard Calorimeter and a Recording device.



SOLE LICENSEES,

ALEXANDER WRIGHT & Co., Ltd.,

1, Westminster Palace Gardens, Westminster, S.W. 1.

DERBY GAS LIGHT AND COKE COMPANY.

Description of the Works.

The Derby Gas Light and Coke Company was incorporated by an Act of Parliament obtained in 1820 for lighting the town of Derby with carburetted hydrogen or coal gas. In 1841, a further Act was granted to the Company "for better lighting with gas the borough of Derby and several parishes and places adjacent thereto." By an Act in 1852, further powers were conferred, and by the Midland Railway (Derby Gas) Act, 1867, an exchange of lands between the Midland Railway Company and the Derby Gas Company was authorized, and provided for a site for new works at Litchurch.

In 1876 and 1890, and also in 1903 and 1906, Acts were obtained to enable the Company to raise additional capital and

Fig. 1.—Eighteenth Century Hand-Beaten Wrought-Iron Gates—Cavendish Street Works.

extend further the limits of supply. The 1906 Act authorized the Company to acquire the two undertakings of the Spondon, Ockbrook, and Borrowash, and Mickleover and Etwall Gas Companies. In 1908, the purchase of the Belper Gas Company and Mr. Strutt's Milford Gas-Works was authorized, and the limits of supply were extended to include the districts supplied by these two undertakings.

By the Derby Gas (Charges) Order, 1921, thermal value was substituted for illuminating power, the charge for gas thereby being based on its potential thermal value, instead of its volume. In 1923, a Special Order was made by the Board of Trade under the Gas Regulation Act, 1920, to enable the Company to acquire additional lands at Litchurch and Belper for gas-works purposes.

The Company's area of supply includes the County Borough of Derby (extended from time to time), and also the districts supplied by the five amalgamated neighbouring undertakings. To-day the Derby Gas Light and Coke Company's limits of supply cover an area of some 85 square miles.

The authorized capital is £589,270, with borrowing powers up to £106,017, making a total of £695,287, of which £492,270 of ordinary stock has been issued, and £55,000 of 4 p.ct. perpetual debenture stock. There are in addition £69,635 premiums on stock sold by public auction, upon which no interest is paid. The total expended capital at Dec. 31, 1924, was £646,490.

The make of gas in 1900 was 595 million c.ft., and last year (1924) it was 1661 millions—being an increase of 1066 millions, or 180 p.ct. The mileage of gas mains in the last 24 years has been increased from 90 to 229, and the number of consumers from 18,234 to 38,851.

The Company do a large and increasing business in the sale of fittings, burners, globes, and shades for lighting purposes, and also by letting out, on simple and purchase hire, gas cooking stoves, fires, and all kinds of gas appliances for domestic and industrial purposes. The latest development is to let-out gas engines on simple hire. The price charged for gas used for lighting and domestic purposes compares favourably with that of most other towns, and special advantageous terms are given to industrial and motive power users.

The chief offices and showrooms are centrally situated in Friar Gate; the property on each side having been purchased to enable the Company to extend the main building when required. There is also a branch office and showroom at Belper.

The declared quality of gas supplied is 500 B.Th.U. per c.ft.

Litchurch Gas-Works.

The Litchurch Works are on the outskirts of Derby, on the east side, some two miles from the centre of the town. They adjoin the London Midland and Scottish Railway, and cover about 21 acres; there being a further 57 acres of land acquired by the Company for future developments. These works are divided by the Derby Canal; "A" works were inaugurated in 1867, and occupy about 10 acres; the new "B" works were begun in 1915, to enable the Company to meet the large increase in demand for gas required for war work. Access to "A" or "B" works is by means of a high-level road bridge, railway swing bridge, and two high-level foot bridges over the canal. From the main entrance of the works, a granite-paved roadway, 47 ft. wide, runs almost the whole length of the "A" section works.

At the right-hand side of entrance is an ambulance room. The Resident Manager's house and works offices are on the same side, a short distance inside the entrance gates.

The Works Laboratory is situated almost opposite to the offices, and comprises office and balance room, physical and chemical test rooms, distillation room, stores, and official gas-testing room.

The recording calorimeters and routine testing instruments are fixed in close proximity to the appropriate gas mains, in an annexe to the station meter house, about ten yards from the works laboratory.

The "A" works are divided into two, each section being a complete unit which can be operated separately or jointly by means of by-passes.

No. 1 Retort House is a cellar house 241 ft. long by 52 ft. wide, and contains 18 settings of 8 C-section retorts, 22 in. by 16 in. by 18 ft. long, or 144 through retorts. The settings are heated by 18 Klonnè regenerative furnaces, and the retorts charged and discharged by De Brouwer stoking machines. The charging machine is fed from continuous overhead coal hoppers of 24 hours' storage capacity. The seals on dip pipes are regulared by Dillamore tar columns, and the suction on each retort bench is controlled by retort house governor.

No. 2 Retort House is a stage-floor house, the same size as No. 1 house, and contains 22 settings—11 beds at the west end being 22 in. by 16 in. C-section retorts, and those at the east end 24 in. by 16 in.—all heated by Klönne regenerative fur-

Fig. 4.—No. 1 Purifier ouse—Litchurch Works.

Fig. 7.—Purifier House for Coal Gas—Litchurch Works.

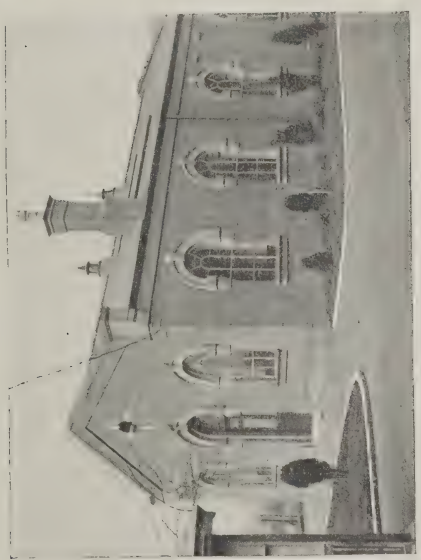

Fig. 2.—Laboratory—Litchurch Works.

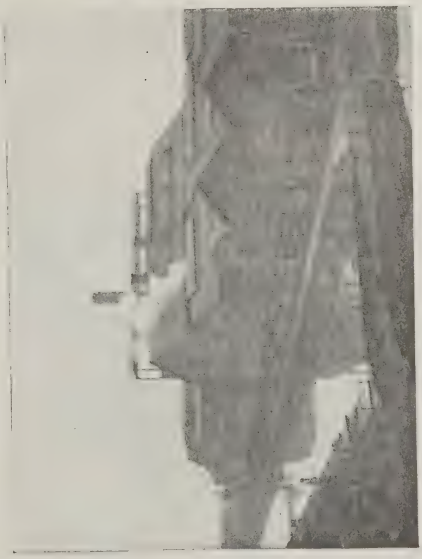

Fig. 5.—"B" Section—Litchurch Works.

naces. The stoking machines are De Brouwer, similar to those in the other house; the coal being fed into the charging machine from overhead continuous coal hoppers.

Each house has a separate wagon tipper, coal breaker, and elevator, constructed to deal with from 40 to 60 tons of coal per hour; the overhead hoppers being fed by longitudinal scraper conveyors. On the opposite side of the houses the hot coke, on being discharged from the retorts, is taken away by De Brouwer longitudinal coke conveyors and cross-inclined elevators, which pass the coke over screens into overhead storage hoppers for loading into railway wagons or carts.

The power for driving the coal and coke handling plants is obtained from gas engines fixed in convenient buildings adjoining the coal breakers, elevators, and conveyors, and varying in size from 25 to 70 H.P. The latter type of engine is in duplicate, and in addition to driving the coal and coke plants for No. 1 house, is belt-coupled to a 45-KW. electric generator, which supplies all the electrical power required for both "A" and "B" works.

Scrubbing and Washing Plant.—No. 1 Section consists of a 2-million c.ft. Livesey tar extractor, a tower scrubber, 12 ft. diameter by 60 ft. high, and a Kirkham rotary washer. No. 2 Section, when completed, will be similar.

Boiler House.—Five Lancashire boilers, each 28 ft. long, three of which are 7 ft. 6 in. in diameter, and two 9 ft. diameter, are fitted with steam superheaters. There are two batteries of economizers for heating the feed water by waste heat. Each boiler is constructed for 160 lbs. w.s.p., and is fitted with a turbine breeze furnace—coke dust or other refuse being used for steam raising.

Pump House.—This adjoins the boiler house and contains, in duplicate, Weir boiler feed pumps, Pearns treble-ram pumps for supplying water from the canal for works purposes, and Lee Howl liquor pumps for supplying ammoniacal liquor to the sulphate of ammonia plant.

Exhauster House.—This contains four sets of gas exhausters (driven by horizontal direct-coupled steam engines) each having a capacity of 120,000 c.ft. per hour. Each set can be coupled to either No. 1 or No. 2 Section.

Purifying House.—No. 1 consists of eight overhead purifiers. Each box is 30 ft. by 25 ft. by 6 ft., and each purifier is fitted with four luteless covers, and Milbourne fasteners and valves. There are four discharging shoots on the bottom of each purifier, the latter being filled by means of an oxide elevator and overhead band conveyor with suitable charging shoots. No. 2 house contains four purifiers, each 30 ft. by 15 ft.

by 4 ft. deep, with water lutes, on ground-floor level, operated by a centre valve. It is intended at some future time to replace these by eight larger purifiers fixed overhead, similar to those in No. 1 house.

Tar and liquor storage is provided under what was formerly a lime shed between No. 1 and No. 2 purifier houses.

Station Meter and Governor House.—This adjoins the purifying houses, and contains two station meters, each of 100,000 c.ft. per hour, with 18-in. to 24-in. connections and by-passes. There are three double-cone water-loaded station governors which control the gas supply on one 30-in. and two 24-in. trunk mains, and there is a smaller station governor for the outlying districts, to which gas is supplied by two high-pressure mains, one 18 in. and one 10 in.

A safety governor is fixed between the inlet and the outlet of the gasholders, so that, if the outlet valves are improperly operated, the gas supply is not entirely shut off.

Naphthalene Washer.—Fixed on inlet main to the gasholders is a 5-million c.ft. per diem rotary washer for extracting the naphthalene from the purified gas prior to its entering the storage holders.

The three gasholders are severally 125 ft. in diameter, 4 lifts; 90 ft. in diameter, 2 lifts; and 140 ft. in diameter, 4 lifts—all in brick tanks. The 125-ft. diameter holder top lift rises above the outside column framing, and is guided by wire ropes. The 140-ft. diameter holder has a flying top lift. These two were formerly two-lift holders, and were converted into four-lift holders to provide additional storage, which now totals 2¾ million c.ft. Including the Railway Company's and two C.W.G. holders, the total storage is 3,900,000 c.ft., which is small for works capable of making 4½ million c.ft. of coal gas and 3½ million c.ft. of C.W.G. per diem. The maximum output of gas from the Litchurch Works is about 5⅓ million c.ft. per diem.

"B" Works.

These works were begun in 1915, to enable the Company to meet the large increase in the demand for gas during the war. It was imperative that additional gas-making plant should be erected and put into operation as quickly as possible. Hence C.W.G. plant was decided upon.

The Generator House, with boiler, engine, and meter houses, form one block of buildings facing the canal on the main roadway, 43 ft. wide, which runs the whole length of these works. This section is designed for an ultimate output of 10 million c.ft. of C.W.G. per diem. The plant at present installed comprises one 2-million c.ft. and one 1½ million c.ft. Humphreys and Glasgow C.W.G. sets. Attached, and serving either plant, is a vertical tubular waste-heat boiler, capable of producing all the steam required by one set. There is sufficient room in the generator house to erect three more C.W.G. sets. In the same building are two Lancashire boilers, each 30 ft. long by 9 ft. in diameter, fitted with superheaters and turbine breeze furnaces, and with a Green economizer at the back, for heating the feed water. There is sufficient room for three more boilers.

Fig. 6.—Operating Stage, C.W.G. Plant, showing Waste-Heat Boiler—Litchurch Works.

The water for steam-raising is softened by a Lassen Hjort plant.

The Blower House contains two Sturtevant fans, each driven by a 55-H.P. Greenwood & Batley turbine; and there is also a 120-H.P. Hodges steam turbo-blower capable of delivering 15,000 c.ft. of air per minute against 30-in. water-gauge pressure.

The Engine House contains two Bryan Donkin exhausters, each of 150,000 c.ft. per hour capacity, coupled direct to vertical high-speed enclosed steam engines, for pumping the gas from the storage holders and delivering it through a 24-in. main to "A" works, where it is mixed with the coal gas on the inlet main to the gasholders. The gas sent over is measured by a 150,000 c.ft. per hour station meter.

Weir service and boiler feed pumps in duplicate supply all water required on the "B" section.

The coke required for the production of C.W.G. or blue gas is carried by the Company's own railway wagons and shunting locomotives to a wagon tipper, is elevated, and stored in overhead coke storage hoppers, and discharged by shoots over screens into the generator by the hydraulic charging ram, thereby maintaining a constant depth of fuel in the generator. A hydraulic lift and bogies are provided as a duplicate coke-handling plant.

C.W.G. Purifiers.—The water gas is purified in four boxes on ground-floor level, each 40 ft. by 30 ft. by 6 ft. deep, with four luteless covers for emptying and filling. These purifiers are in a covered shed 141 ft. long by 49 ft. wide, with revivifying sheds on each side, 37 ft. wide, for the full length of the building. The gas through the four boxes is controlled by Milbourne inlet and outlet valves and connections, all of which are readily accessible. For filling and emptying, small electric travelling cranes, with tip buckets, run the length of the house alongside the boxes.

C.W.G. Holders.—Storage accommodation is provided by two gasholders in steel tanks. The ¼-million c.ft. holder is spiral-guided, and the ½-million c.ft. is a three-lift one, with outside guide framing.

"A" and "B" are works connected by a works telephone system to the various sections, whereby hourly records are obtained of the different operations.

Chemical Plant.—The sulphate of ammonia plant is contained in a building about 120 ft. long by 62 ft. wide, one-half of which is reserved for storage of sulphate. This plant was recently supplied and erected by the Chemical Engineering Company. It contains several new features, and is capable of producing 6 tons of dry neutral granular salt per day. It consists of a combined fixed and free ammonia still, with liming chamber and closed type of saturator fitted with a Wilton discharger. A small coil condenser provides the liquor for spraying and neutralizing the salt, which is carried on a steel belt conveyor over vacuum pipes, and then discharged into a horizontal belt-driven dryer fitted with steam pipes. After drying, it is delivered into bags attached to an automatic weighing machine.

Sufficient room has been allowed for the erection of two additional similar units. It is intended to remove the concentrating ammonia liquor plant from the old sulphate buildings, and to re-fix it in the new house.

The effluent gases from the still are cooled by tubular condensers, and finally by 800 ft. run of 8 in. diameter water-cooled cast-iron pipes. They are afterwards treated by open oxide purifiers.

The Tar Dehydrating Plant is a Wilton coil dehydrating plant, to which has been added extra coils to enable No. 1 Road Board Specification tar to be made. This will deal with about 20 tons of crude tar per 24 hours. Direct-fired stills are now in course of erection to produce No. 2 Road Board tar for road purposes.

Cyanide Plant.—The whole or any portion of the coal gas made may be freed from hydrocyanic acid content by being passed through a Pelouze tar extractor and a Holmes cyanide washer. The washing medium is prepared by precipitation of iron from copperas by means of a light alkali. From the circulating liquor, prussiate of soda is recovered in the form of yellow crystals by the Davies-Neil process.

"B" Works New Coal Gas Plant.

A start has been made by the erection of a large steel-framed building, containing four overhead purifiers, each 45 ft. by 40 ft. by 6 ft. deep; each box being fitted with four luteless lids secured by Milbourne's fastenings and with discharge shoots on the bottom. A new feature is that the inlet and outlet pipes for controlling the gas are overhead, and thus readily accessible. The oxide is elevated by a bucket elevator, which feeds on to a rubber band conveyor running the whole length in the centre of the house; and a travelling discharger with shoots enables the oxide to be filled into the purifiers with a minimum of labour. The oxide handling plant was recently supplied and erected by the Ewart Chain Belt Co., Ltd., of Derby. The ground floor under the purifiers and adjoining the revivifying shed is used for the preparation and storage of oxide.

Fig. 8. Entrance—Cavendish Street Works.

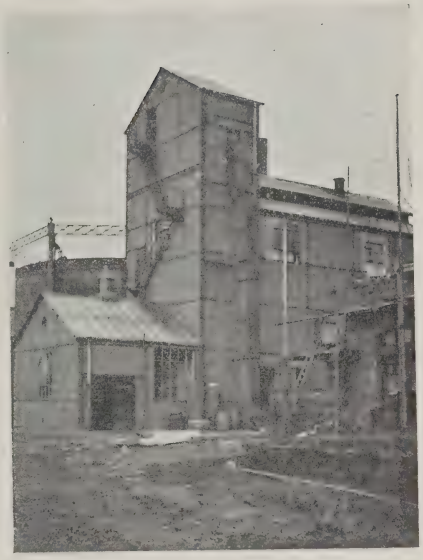

Fig. 9.—Tully Plant—Belper Works.

Station Meter House.—The meter house adjoins the purifier house and contains a 200,000 c.ft. per hour Parkinson station meter with the necessary 24 in. diameter valves and connections. The purifying plant is so designed that it can easily be doubled at any future time.

It is intended that the new "B" section coal-gas plant will be in 5 million c.ft. per 24-hours units, each section to be worked separately, similar to the "A" section.

Ample space is allowed for railway sidings in all directions, for future extensions, and especially for storage of coal, coke, and other residual products.

Cavendish Street Works.

This is the Company's original manufacturing station. It was erected in 1820, and has been entirely re-built and extended from time to time, and now covers an area of some four acres. These works are situated directly at the back of the chief offices in Friar Gate. It may be recalled that the first D.B. stoking machine was installed at the Cavendish Street Works and aroused much interest at the time. The carbonizing plant consists of both horizontal and vertical retort settings. There are six through horizontal beds of 8 ⏀ shape, 21 in. by 15 in. by 18 ft. retorts, operated by the D.B. latest type of combined machine. This is fitted with the latest pattern discharging ram; the old telescopic lengths, together with their catches and stops, being dispensed with. The Oxford safety device for holding-up the body of the machine in case of the hoisting chains failing is also fitted, together with electric cut-outs to prevent overwinding, &c. Extension of the power plant in connection with this machinery and the vertical installation is now under consideration.

The Vertical Retort House.—The bench, till it was recently demolished, comprised six beds of Wilson-Glasgow continuous intermittent vertical retorts—36 in all—having a nominal capacity of 1,000,000 c.ft. per diem. Coal is delivered through a single roll crusher, or direct to a gravity-bucket elevator conveyor which feeds overhead hoppers of 48 hours' capacity. The new bench is at present being erected by West's Gas Improvement Company, and will consist of five beds of their latest design. There will be eight 20-ft. retorts per bed, or 40 retorts, having a productive capacity of 1,400,000 c.ft. per diem. The existing steel stancheons, overhead bunkers, coal breaker, and G.B. elevator and conveyor, and the foul gas main, will all be incorporated in the new installation. A Kirke waste-heat boiler will be erected on the site of one of the old vertical retort beds, and it is expected that this boiler will give an evaporation of 3000 to 4000 lbs. of water per hour. The entire work will, it is anticipated, be completed in time for next winter's demand.

The exhauster engines at this station are of the vertical enclosed type, by Messrs. Robey & Co.; and the exhausters, by the Bryan Donkin Company, Ltd., have a capacity of 2 million c.ft. per diem.

The washing plant comprises a Livesey washer, a tower-scrubber, and a Holmes rotary washer. There are two sets of purifiers. No. 1 house contains four boxes, each 20 ft. by 14 ft. by 3 ft. 6 in., operated by double-faced Cockey centre valve, so that the boxes may be worked either three or four at a time. No. 2 house contains four boxes, 30 ft. by 15 ft. by 4 ft., operated by a Weck centre valve.

The gasholders, three in number, have a capacity of 500,000 c.ft. The governor house contains the station meter and station governor, a separate governor for the outlying districts, and a safety governor to correct improper gasholder valve operation. The exhauster house contains two sets of gas compressors, by the Bryan Donkin Company, Ltd., which may be used either for high-pressure distribution in the town or for pumping gas at 2 lbs. per sq in. pressure to Belper (8 miles), and feeding various villages through district governors *en route*.

The mechanics and blacksmiths shops have recently been enlarged; and at these works are garages for the steam wagons, lorries, motor vans, and cars required in connection with transport over the Company's extensive area of supply. The works office and chief stores, situated at the entrance to the Cavendish Street Works, have recently been extended, to allow more room for the numerous stores now required in connection with the distribution department.

An official testing station for these works and the works' laboratory have recently been erected, and are controlled from the Company's well-equipped main laboratory at Friar Gate.

The laboratory comprises the top floor of the general offices, and includes an office, photometer room, dark room, laboratory, balance and physical test room, store room, &c.

Belper Gas-Works.

The Belper Works of the Company, eight miles from Derby, are situated on the banks of the Derwent, and were purchased from the old Belper Gas Company about eighteen years ago. They are now connected by a high-pressure main to the Cavendish Street Works. A considerable part of the total area of 6½ acres is available for extensions; the present output being just over 100 million c.ft. per annum.

A railway siding adjoins the retort house, thus facilitating handling of coal and dispatch of tar and liquor. The carbonizing unit consists of 6 beds of 8 stop-ended ⏀-shaped retorts (operated by hand and heated by regenerative furnaces), and a Tully gas plant of 500,000 c.ft. capacity per diem, erected in a steel-framed building. This plant is utilized as far as possible to supplement the output from these works. It is fitted with a superheater, and by the addition of oil can produce high-quality gas, should this be required at rush periods. Temperatures are controlled by electrical pyrometers. This auxiliary plant has been very useful, and, considering its necessarily spasmodic operation, the results obtained are quite good.

Two additional Lancashire boilers, 28 ft. by 7 ft. 6 in., with superheaters in each case, have recently been installed. These boilers are suited for a w.s.p. of 200 lbs. per sq. in., and are fitted with turbine breeze furnaces.

Scrubbing and Washing Plant.—This comprises a P. & A. tar extractor, a Livesey washer, a Kirkham washer, and a Walker scrubber. The purifiers, 25 ft. by 20 ft. by 5 ft., are dry sealed, and are operated by Milbourne patent valves. The new section of the works is laid out for a daily output of 1,000,000 c.ft.

The gasholder, of 500,000 c.ft. capacity, is spirally guided; and there is a small relief holder (for Tully gas) connected to the hydraulic main in the retort house. The supply to the Belper district is governed by a 15-in. Parkinson double-coned station governor; and a second outlet from the holder feeds gas to the high-pressure main running back to Derby.

Fig. 10.—Entrance to Showroom, Friar Gate.

The works are equipped with mess room, office, and laboratory containing the official testing apparatus.

Distribution Department.

The showrooms are on the right-hand side of the main entrance to general offices, with a reception room (oak panelled), and a showroom divided into a number of recesses to exhibit various patterns of modern gas fires and fittings for lighting. The rear portion of the showroom is partitioned off by oak panelling, and contains a number of gas cooking stoves, and water-heating appliances. There are a porcelain bath, sink, &c., to enable various apparatus to be demonstrated in actual operation. An adjoining room is fitted with show-cases to display lighting fittings, burners, glassware, silk shades, &c.

The distribution office and shops comprise accommodation for the Superintendent, office staff, inspectors, and foremen; and there are also repair shops for dealing with meters, fittings, stoves, &c.

For many years the Company have supplied, and fixed complete, gas engines on hire-purchase; and recently it was decided to extend ordinary hire facilities to gas engines. The Company inspect, test, and maintain gas engines at a nominal charge; the result being that those who use gas for power purposes can rely upon a continuous power supply at the low figure of about ½d. per B.H.P. hour.

The Company employ a specially trained staff of fitters for piping houses, and fixing lighting installations, gas cooking stoves, fires, geysers, water-heaters, and all kinds of gas appliances for domestic and trade purposes.

Inspectors and canvassers keep the Company in close touch with consumers, and advise and estimate for their wants and requirements in all matters pertaining to the use of gas for lighting, heating, and power.

AT THE FULHAM GAS-WORKS.

The members who had elected to take part in the visit on Thursday afternoon to the Fulham Works of the Gas Light and Coke Company numbered 200 and more, and included the President (Mr. Ferguson Bell). They assembled at the Chief Offices of the Company in Horseferry Road, where Mr. Thomas Hardie (the Chief Engineer) awaited them, and punctually at the appointed time set out in motor coaches for the works. To the great disappointment of both the Governor (Mr. D. Milne Watson) and Mr. Hardie—and also, it need hardly be added, of the visitors—neither of them was able to accompany the party; it being explained that they had to remain in town to attend a meeting there in connection with the gas industry.

On arriving at the Imperial Wharfe entrance to the works, the members were received by Mr. A. H. Solomon, who offered them a cordial welcome, and in every way proved an admirable host. It was noted at once—from the very moment of forming the parties for inspection—that the most complete arrangements had been made by the Company for the comfort of their guests, whose path from start to finish proved a smooth—if somewhat hot—one. Many points about the Fulham Gas-Works struck the members of the Institution favourably, and not least among these must be placed the efficient organization which was revealed in the planning and carrying out of the programme. Mr. Solomon was everywhere, and all the officers detailed to assist were everywhere; no one had need to go without any information he might desire; and yet there was no crowding at all. Mr. Samuel Glover, with long and varied experience of visits to works, was warm in his praise of the excellence of the organization and of the services of the guides; and the reception which his remarks met with showed how thoroughly his hearers were in accord.

So much having been said, it would be unfair to leave the story incomplete; so we will add that the visitors were divided into six parties, all neatly badged, and were placed under the leadership of (1) Mr. Grogono, (2) Mr. Calvert, (3) Mr. Davies, (4) Mr. Tanner, (5) Mr. Parkinson, and (6) Messrs. Ball and Holdway. To these parties were attached the following members of the engineering staff: (1) Messrs. Hunter, Richmond, and Barclay, (2) Messrs. Mitchell, Anderson, and Royle, (3) Messrs. Wood, Wallington, and Tutton (Construction Department), (4) Messrs. Stewart, Culbertson, and Lacey, (5) Messrs. Hutchence and Cooper (Construction Department), (6) Messrs. Sheridan and Phillips (Construction Department). In their tour the visitors were further aided by an illustrated brochure, the description contained in which is given below.

From this description, some idea will be gathered of how much there was to be seen. It is always a treat to be privileged to inspect constructional operations on a gas-works; and the treat was offered here in no unstinted measure. First of all (taken in the order of inspection) there was the strengthening of over 290 ft. of river wall; and the crane track, upon which two electric cranes, of 125 tons per hour each, will operate. A reinforced concrete hopper to store 2000 tons of coal is being constructed; and under this has been completed the conveyor pit, in which will work an endless and reversible (for the purpose of loading barges at either end in the future) belt conveyor, 250 tons per hour, at 260 ft. per minute, delivering at the east end on one of a series of belts conveying the coal into retort houses some 600 yards distant or to the storage ground of 40,000 tons. The coal will be reclaimed from store by means of an 8-ton electrically-driven crane. Large reinforced concrete purifiers are also being constructed. All the complete new plant referred to in the description to which the attention of readers has already been directed has had to be erected on the very limited ground area which was at disposal after pulling-down existing small plant, and the usual manufacture at the station has had to be carried on during the reconstruction, alterations to mains, &c.

As much time as was available was naturally devoted to the carbonizing plant; the reconstruction of No. 1 retort house having been in hand during the past eighteen months. There are sixteen settings of eight Glover-West vertical retorts, built to produce 7 million c.ft. of gas in 24 hours, carbonizing 450 tons, at 70 therms per ton. The retorts are of the Leigh type; and the settings are fully equipped with waste-heat boilers. In the retort house a full set of drawings of the installation were displayed. These drawings included arrangement drawings of the installation as a whole, together with a set of detail drawings of the retort settings and of the working parts of the plant. These detail drawings will be handed over to the engineers in charge of the operation of the retort house. They are fully marked with reference numbers, by which every moving and renewable part can be identified—thus greatly facilitating repairs and renewals when such become necessary. It may be mentioned that coal is weighed automatically when entering the retort house, while on the belt conveyor; while coke is also weighed automatically before being charged into the producers.

On reaching the new stove shops, most welcome and most bounteous hospitality awaited the visitors—most of whom by that time showed evident signs of having borne the "heat and burden" of the day. Mr. Solomon then explained the cause of the regretted absence of the Governor and the Chief Engineer. He remarked that the Institution, already a great body, promised in the future to be of still greater importance. They as members should honour those gentlemen who, within recent years, had brought the Institution to the position which it now occupied. So far as the Fulham Station was concerned, it had been a great anxiety to them to get the place into a fit state for the visit. Fulham had always enjoyed the reputation of being neat and tidy; but this was doubly hard to maintain with

VIEW OF THE STATION FROM THE AIR.

so much reconstruction work on hand. He hoped that what they had seen had proved of interest to them. Mr. Samuel Glover, in terms which met with the approbation of all present, voiced their thanks to the Governor and Directors of the Gas Light and Coke Company for their invitation to visit the works, and for the hospitality that had been extended to them. He also made graceful and well-deserved acknowledgment of the attentions of Mr. Solomon and the services of the guides. Notwithstanding what had been said by Mr. Solomon as to the conditions of the works, he could assure him of the great joy experienced by gas engineers in visiting a works under reconstruction. Mr. Hubert Pooley seconded the vote of thanks, of which Mr. Solomon made suitable acknowledgment.

DESCRIPTION OF THE WORKS.

This station was one of the original works of the Imperial Gas Company, which amalgamated with the Gas Light and Coke Company in 1876. At that time the Engineer of the works was Mr. E. Kirkham, who was the designer of the station as it then existed.

Site.—The site covers an area of 29½ acres, and in part adjoins the North Bank of the Thames a short distance above Chelsea Railway Bridge. A creek from the river, terminating in a dock, enables coal barges—loaded at the Company's Beckton Works—to be unloaded by three wharf-side cranes. The works is also connected by direct siding with the West London Extension Railway; and coal, bricks, and other goods can be received by this means.

The tar, liquor, and oxide of iron are all sent away, for working up, by barge to the Company's Chemical Works at Beckton.

Capacity.—The works has a present daily winter output of 10½ million c.ft., but the extensive reconstructions now nearing completion will raise this to over 17 million c.ft. daily. At the same time improved means of coal reception, so as to unload direct from the Company's own colliers, are being installed upon the river front.

Existing Plant.

Coal Gas Plant.—No. 3 retort house contains 200 retorts, 23 in. by 16 in. by 20 ft. long, in 20 beds operated by a Fiddes Aldridge machine. The house carbonizes 230 tons daily, and produces therefrom 3 million c.ft. of gas.

No. 4 retort house contains 144 inclined retorts in 18 beds. It is not much worked at present, but will make 2 million c.ft. daily.

No. 5 retort house is similar in type to No. 3, but the retorts

CARBURETTED WATER GAS AND VERTICAL RETORT HOUSES

are 22 ft. long. The Fiddes Aldridge machine is of the latest type. The house carbonizes 250 tons of coal, and produces 3,250,000 c.ft. of gas daily.

In all three houses, coke handling is by drag-bar conveyors into outside loading hoppers.

Water Gas Plant.—This plant, together with the attendant boilers, blowers, and other machinery, is housed in one row of buildings adjacent to No. 1 retort house. It consists of two twin-generator Humphreys & Glasgow carburetted water gas units, each of 1½ million c.ft. daily capacity, and one Humphreys & Glasgow 1½ million c.ft. daily capacity blue water gas unit. All three sets are equipped with waste-heat boilers, stage clinkering floor, and, subsequent to the present reconstruction, will have mechanical coke handling plant.

Exhausters.—These are housed in one building. There are eight sets, seven of which are by Messrs. Gwynne & Co., and one by Messrs. Waller & Co. The house also contains a Reavell positive booster driven at 800 r.p.m. by a 90-H.P. motor.

Ammonia Plant.—At the rear of the exhauster house is the ammonia purifying plant. The gas is exhausted before passing through the condensers. There are two sets of atmospheric, and two sets of water-tube (Clapham), condensers. These are followed by three sets of washing plant, each consisting of one Livesey washer and one rotary washer-scrubber. From this point the gas passes across the works by two 24-in. mains to tower scrubbers, where the last traces of ammonia are arrested.

Purifiers.—There are four sections of purifiers. The two of more recent construction, allocated to coal gas, are luteless boxes arranged overhead, and each section consists of five boxes. Each box measures 48 ft. by 30 ft. by 6 ft. 6 in. deep, and has a capacity of 130 tons of oxide when laid in two tiers on wooden grids.

The two remaining sections for water gas are of old design, and have counterbalanced water-luted lids. Each section is worked in two streams of three boxes. Each box measures 37 ft. by 20 ft., and holds 70 tons of oxide. The coal gas, before entering the station meters, is washed with gas oil, for the removal of naphthalene.

Station Meters.—There are three meters, two of 250,000 c.ft. per hour for coal gas placed partly below ground, and one of 150,000 c.ft. per hour for water gas. All are in the open.

Holders.—There are five holders of a total capacity of 8½ millions. One 2 million c.ft. holder has been removed recently for reconstruction. All have brick and puddle tanks.

Electric Generating Plant.—All the current at present required on the works is generated in the room adjoining No. 3 retort house by means of two 150-KW. vertical gas engine driven sets, producing 220 v. direct current. Three smaller units have been removed recently to make room for more modern and enlarged plant, described later.

Steam Plant.—Apart from the water gas plant, all steam required is produced at 120 lbs. per sq. in. pressure in a range of six hand-fired Lancashire boilers of the Thompson dish-ended type, 30 ft. long by 8 ft. 6 in. diameter. The furnaces are all of forced-draught breeze-burning type, and the fuel is to a large extent mechanically handled.

Coal Handling Plant.—At the present time coal is brought in barges into dock, and unloaded by grabs. It is then conveyed by belts to a central crushing plant, and distributed therefrom to the several retort houses by belt conveyors, and thence to the bunkers by house conveyors which are of the push-plate type in Nos. 3 and 4 houses, and the shuttle rubber belt in No. 5 house. The whole belt conveying handling scheme has been installed recently.

The store of over 20,000 tons of coal in the yard was formed by means of small trucks fed by a push-plate conveyor which has now been displaced.

Water Supply.—The deep well, constructed in 1907, is a 12 in. borehole, 501 ft. deep. Water is raised by a 75 H.P. gas engine driven Reavell air compressor, or alternately by an Alley and Machellan compressor direct coupled to a 65 H.P. motor. The plant is capable of dealing with 8000 gallons per hour.

Reconstruction Work.

This work embraces the erection of a complete plant throughout for the production of 7 million c.ft., or 35,550 therms, per day.

No. 1 Retort House.—The reconstruction of this house has been in hand during the past 18 months. There are 16 settings of eight Glover-West vertical retorts (33 in. by 10 in. by 25 ft.), built to produce 7 million c.ft. in 24 hours, carbonizing 450 tons at 79 therms per ton. The retorts are of the Leigh type, and the settings are fully equipped with waste-heat boilers.

Condensers.—A battery of atmospheric condensers, erected by the Company, consisting of 12-in. zigzag pipes, is supplemented by two water-tube condensers erected by Messrs. W. C. Holmes & Co., of Huddersfield.

Exhauster House.—Nearby, a smaller building originally used as a lobby and store has been enlarged, to house three Donkin exhausters, each of 175,000 c.ft. capacity per hour. The building also houses a small Waller air exhauster for the purifiers, and sundry pumps for tar and liquor.

Washers.—For tar removal there are two Livesey washers, each able to deal with 3½ millions per day, supplied by Messrs. Cockey & Sons. For ammonia extraction there are two rotary washers, each of 7 million c.ft. per day capacity, built by the Wheesoe Foundry Company.

Purifiers.—Reinforced concrete purifiers are being constructed nearby. The boxes are elevated above ground. There will be two sections of four vessels, each vessel measuring 50 ft. by 35 ft. by 6 ft. 6 in. Above, there will be a revivifying floor, to which the oxide will be raised by an elevator, and distributed, after passing through a disintegrator, by a belt conveyor. The ferro-concrete is being constructed by Concrete Piling, Ltd., the oxide handling plant by Messrs. R. Dempster & Sons, and the steel covers by Messrs. E. Cockey. The cast-iron mains and connections, supplied by the Stanton Ironworks Company, will be fixed by the Company. These and the mains in the exhauster house are the only ones under the ground. The remainder, of steel, will be run upon supports overground.

Meters.—There are two meters, each of 250,000 c.ft. per hour capacity, by Messrs. Parkinson & Co., erected in an old gasholder tank. An additional 36-in. main from meters to gasholders has been installed to handle the gas from this new plant.

No. 4 Gasholder.—The demolition of this is just completed. It was built in 1856, and was in excellent preservation, but was removed in order to obtain further storage capacity. Messrs. R. & J. Dempster, Ltd., are the Contractors for the erection of a four-lift spiral-guided holder of 4 million c.ft. capacity, which is double that of the former holder in the tank.

Water Tower.—Owing to the building of the new purifiers upon the site which included the water supply tank to the works, it has been necessary to provide a new tank. This has been constructed in reinforced concrete, to the Company's design, by Concrete Piling, Ltd., upon a site by the railway siding. Its capacity is 60,000 gallons, and it is 77 ft. high.

Coal Plant.—At the river front the quay wall is being strengthened by the driving of 35 ft. concrete piles (Contractors, Messrs. Saxild & Partners) for the purpose of supporting two electric cranes (capacity, 7½ tons maximum load) and to enable a berth to be provided for the ships. The coal will be unloaded into a reinforced-concrete bunker (capacity, 2000 tons), from which it will be conveyed by belts to a crushing station, and thence to the retort houses—a total distance of 600 yards—or to the storage ground, at the rate of 250 tons per hour. Coal is reclaimed from the stock heap by an 8-ton travelling crane with a 60 ft. luffing jib at 150 tons per hour, and delivered to the belt conveyor system. The conveying plant and stocking plant are being erected by the Mitchell Conveyor Company.

Electric Generating Plant.—To provide further power, and at the same time effectively to utilize the steam from the waste-heat boilers, in the power house there is in the course of erection one 500 KW. D.C. 220-240 v. turbo-generator and condenser, and one 250 KW. A.C. 500 v. 3-phase 50-period turbo-generator and condenser, together with an air pump for each set, and circulating pumps in duplicate, switchgear, &c. In addition a motor generator has been installed as a connecting link between the A.C. and D.C. supply. The alternating current is arranged for the long-distance coal plant supply, and the direct current for the more local supplies. The Contractors for this plant are the Lancashire Dynamo Company, Ltd., who are supplying turbines built by Messrs. C. A. Parsons, Ltd.

VISIT TO THE NATIONAL PHYSICAL LABORATORY.

The party visiting, by permission of Sir Joseph Petaval, K.B.E. (Director), the National Physical Laboratory, consisted of about one hundred, and were in charge of the Secretary of the Institution.

They were received, on behalf of the Director, by Mr. G. R. Edwards, Assistant Secretary. The arrangements made for conducting the members and their ladies (of whom there was a good number) were perfect.

Perhaps the feature which proved of the greatest interest was the William Froude National Tank. In 1908, by a gift of £20,000 from Sir Alfred Yarrow, Bart., the well-known torpedo-boat builder of the Clyde, the construction of the tank was commenced. Completed in 1911, it consists of a concrete tank 550 ft. long, 30 ft. wide, with a depth of water of 12½ ft. in the centre. Experiments on models of ships are carried out with the object of improvement in ship design and propulsion. The models are made of paraffin wax in a special cutting machine with flying cutters which reproduces exactly the lines of the ship as designed by the naval architect. By means of a spoke-shave, the model is finished-off carefully by hand. It is placed on the bed of the machine with the keel uppermost. The apparatus for determining the water resistance to the motion of the model, and for making other required measurements, is installed on an electrically-propelled carriage which spans the tank and runs on rails laid on either side. The equipment includes apparatus for producing waves so that tests of models in rough water can be carried out. A false bottom enables the effect of shallow water on resistance, steering, &c., to be studied. Tests on propellers and on models fitted with propellers, form part of the routine work. The drawings of a ship received on (say) Monday morning can be worked upon, the model

produced and tested, and a report of its performance sent to the client, if needs be, on the Saturday following. A test costs £140 to carry out; but it is quite possible that the reduction of horse-power resulting from the disclosure of the tests may save that amount in the cost of fuel in one voyage of the ship itself.

The experiments are supplemented by full-scale observations on the ships themselves. The Suez Canal has been visited to study the effect of shallow water on the steering of actual ships, and voyages have been made in rough weather to obtain data relating to the motion of ships in waves, for comparison with the conclusions derived from the researches conducted in the tank.

Another department which attracted considerable interest was the Sir Julius Wernher Metallurgy Building, the gift of Sir Julius in 1911, to advance the science of metallurgy. The workers here deal with the physical and mechanical properties of metals and alloys, in which the proportions of the different constituent metals are varied over a wide range. Aluminium-copper, aluminium-copper-nickel, aluminium-copper-manganese-silicon, &c., have been examined, as also the effect in the production of such alloys for practical use, of different heat and mechanical treatment, and the various processes which must be employed in the application of the materials to constructional purposes. Microscopic and X-ray examinations of and structure of the metal or alloy to mechanical, thermal, and electrical tests of the resulting products are carried out.

The physics, electricity, metrology, and engineering departments were also seen, and in the aerodynamics department was shown the method of testing aeroplanes, propellers, &c. It was formed in 1909 at the invitation of the Government.

Tea was served at the conclusion of the visit in the spacious canteen. There were flowers, grown on the premises, for the ladies. A vote of thanks was proposed by Mr. C. Dru Drury, member of Council.

THE INSTITUTION AT OLD KENT ROAD.

Visit to the Chemical and Physical Department of the South Metropolitan Gas Company.

PERHAPS the best indication of the remarkable interest of the visit of a section of the Institution of Gas Engineers to the Chemical, Physical, and Industrial Laboratories of the South Metropolitan Gas Company at Old Kent Road was that, almost before one had realized the fact, the visit was concluded, and one was returning to Westminster. And yet the tour of inspection had lasted two-and-a-half hours—and this on an afternoon when the thermometer registered 87 degrees in the shade!

Motor coaches conveyed the party, which numbered about a hundred, from the Institution of Civil Engineers to the Old Kent Road Station of the Company. The weather was delightful, and even Old Kent Road was robbed of its customary drabness. On arrival at the works, the visitors were divided into small parties, and without delay commenced an inspection which proved to be, as Mr. C. F. Botley, the new President of the Institution, so aptly described it, a "real intellectual treat."

THE CHEMICAL SECTION.

This was visited first. On entering the laboratories, one is immediately impressed—and the impression is enhanced by closer inspection—with the general note of cleanliness. There is that atmosphere of orderliness which makes for proficiency.

Attention was first of all drawn to an apparatus for carrying-out trial-carbonizations for determining the effect of temperature, rate of heating, physical and chemical nature of coal, &c., upon the yield and nature of products obtained. Specimens of coke and tar obtained in this apparatus showed the effect of different rates of carbonization; and other specimens of coke demonstrated the effect of blending different materials with the coal for the purpose of avoiding expansion. Specimens of briquettes of 70/30 coal-coke mixtures, carbonized at high and low temperatures, and exhibits showing the effect of the size of particle upon the nature of coke obtained from coal-coke mixtures next claimed attention. The visitors passed on to examine an apparatus used for comparison of the activity of various catalysts in connection with the removal of carbon bisulphide from gas. It was explained that the best results are obtained from a nickel-thoria catalyst; the velocity of the reaction with this compound being two or three times as great as with the original nickelized fireclay. There was also a model of a sulphur extraction plant for testing-out modifications suggested from the results of investigations on the small scale in the laboratory. It is not possible here to detail all the interesting exhibits, which evoked the praise of the visitors from two points of view—the intrinsic value of the exhibits themselves, and the excellent way in which they were set out.

On the subject of the removal of hydrogen sulphide from gas, there was a demonstration of the methylene blue test for the quantitative determination of minute traces of hydrogen sulphide. This colorimetric test is based on the interaction of hydrogen sulphide with dimethyl-*p*-phenylenediamine and ferric chloride in acid solution, to give methylene blue. The hydrogen sulphide is primarily absorbed in ammoniacal cadmium chloride solution and liberated for the reaction by the addition of acid. Nearby was an apparatus for introducing measured traces of hydrogen sulphide into coal gas, and demonstration thereby of the sensitivity of the Referees' testing apparatus. There were exhibits demonstrating the causes of the occasional contamination of completely purified gas by hydrogen sulphide upon storage in gasholders; and the bacterial origin of the hydrogen sulphide, and its suppression by the use of sterilants.

TAR FOR ROAD SURFACING.

One of the most interesting features in the Chemical Section was a well-planned and convincing demonstration that tar suitably treated could be applied to roads without endangering fish life—a subject which of late has received much publicity.

Explanation was given of the systematic tests of tar for fluidity or viscosity, volatilization, binding power, and resistance to compression and recompression; and there was a demonstration of a disinfectant fluid prepared by an emulsifying agent, which, unlike soap, gives a product unaffected by hard water.

The visitors passed on to examine an apparatus for determining volatile matter in coal under conditions more precise than those laid down in the so-called "American Test." Another highly interesting item was an apparatus for determining the ignition point of coke.

A demonstration of corrosion specially dealt with the corrosion of gasholders in which metallic surfaces are brought into contact with water. The galvanic nature of such corrosion was demonstrated, together with the possibilities and limitations of methods of preventing it.

INDUSTRIAL SECTION.

General admiration was expressed of the Industrial Demonstration Laboratory. This constitutes a general exhibit of industrial appliances, furnaces, &c., which have either been designed and erected to meet the special requirements of consumers, or have recently been submitted for examination. In this exhibit are included muffle and crucible furnaces, fish-frying ranges, apparatus for the manufacture of confectionery, and various types of industrial burners. The value of such laboratories is becoming more and more appreciated; and several of the larger undertakings in industrial centres have come to regard them not merely as desirable, but as essential.

In the Burner Workshop the visitors were able to see the production of ejector discs. Orifices of standard dimensions are produced in discs of nickel alloy, which are simultaneously cut from the sheet metal by specially designed machines. In order to produce smooth passages for the efflux of gas, the discs are burnished by hand. They are then mounted in seatings cut in the disc-holder, and are spun, so as to ensure that no leak can occur between holder and ejector disc. The orifices are tested to ensure that the jet of issuing gas will be directed axially down the burner tube. For this purpose a jet of gas issuing from the ejector orifice is ignited, and the ejector rotated about its axis. Any departure of the stream of gas from an axial direction is clearly seen. A system of limit gauging for the standardization of all component parts was demonstrated. These standardized parts are assembled into a burner which is examined for symmetry, alignment, &c. The assembled burners are placed on a bar supplied with gas at a pressure of 25 tenths water-column, and each burner is lit for a period of half-an-hour, and the character of the flame in each burner visually examined. Burners exhibiting defective flames are rejected. The consumption of each burner is determined in order to ascertain that it falls between specified limits. A similar procedure of standardization and examination is applied to the production and assembling of gas fires, and street lighting, high-pressure, and cluster burners.

PHYSICAL SECTION.

Arrived at this Section, inspection was first made of the photometer room. This is equipped with a photometer bench enabling the radial distribution of illumination from sources of high or low candle power to be carried out expeditiously. A complete survey of any source occupies about half-an-hour. An incandescent mantle, standardized against the Harcourt pentane 10 c.p. lamp is employed as a secondary standard. The bench was shown equipped for the measurement of the radial distribution of illumination from a street lamp in which reflection is utilized to effect concentration of considerable illumination in directions approaching the horizontal.

Illumination by a "Daylight" mantle was compared with that given by an ordinary mantle; and the determination of the intensity of various parts of the spectrum of a "Daylight" mantle by means of the Hilger-Nutting spectrophotometer was shown.

Very interesting was the comparison of noises made by various gas jets and burners. A number of triode valves are employed to amplify and rectify a microphonic current pro-

duced by the noise. The microphone employed is of special design; and the sensitivity of the microphone and amplifier is practically constant for all wave lengths. The galvanometer deflection produced thus depends only on the intensity of the sound incident upon the microphone diaphragm.

Of particular interest was a high-pressure gas governor. A constant pressure is maintained within a cylindrical chamber closed on one side by a diaphragm. Any variation of pressure occurring on the outer side of the diaphragm opens or closes a paraboloidal valve, whereby constancy of pressure is maintained at the outlet from the governor. The device can be employed to construct governors operating either at high or low pressures, and was shown operating at a pressure of about 15 lb. per sq. in.; this being maintained constant at an orifice through which air at this pressure was discharged while the supply pressure varied from about 20 to 70 lbs. per sq. in. The discharge was utilized to illustrate the deficit of pressure occurring in a jet of gas—a phenomenon to which the collection of dust round the jet orifice is attributable.

Before concluding this brief and inadequate description of the exhibits, we will refer to a directional form of hot-wire anemometer. Two fine heated wires are arranged in close juxtaposition in the flow tube. The wire upon which the flow is first incident experiences the greater cooling effect—in fact, for slow flows the second wire may experience a heating effect, attributable to the transport of heat from the first wire. The differential effect is utilized to indicate the direction of flow in the system.

Thanks to Dr. Carpenter and his Staff.

After the inspection the party assembled in the Staff Dining Hall, where tea had been provided.

Mr. C. F. Botley said it would be inappropriate if they did not voice their thanks to Dr. Carpenter and his staff for what had proved a real intellectual treat. The standard of working which the South Metropolitan Company set was well known to them all; and they had enjoyed the opportunity of seeing how this standard was kept up. They had been able to appreciate how the Company were investigating problems of vital importance; and they would all be glad to hear that Dr. Carpenter had told him that the Institution of Gas Engineers could have the benefit of the information accruing from the research in the Company's laboratories. [Applause.] He had known the South Metropolitan Company all his life, and it had always been a source of inspiration to him. He had the greatest pleasure in proposing a vote of thanks to Dr. Carpenter and his staff. If those present only remembered a fraction of the information which they had gained through the visit, they would benefit exceedingly.

The vote of thanks was seconded, and carried with acclamation.

Dr. Carpenter, who, on rising, was greeted with prolonged applause, said he was very gratified with such a warm reception on such a warm afternoon. The Institution, as a result of their inspection, had received a mental picture which they should register carefully. Work of a character analogous to that carried out in the laboratories of the South Metropolitan Company was being undertaken by the electricity industry, who were busily investigating the various phases of the use of electricity for heating and lighting. They were dealing with such questions as the efficiency of electric lamps, the influence of inert gases, the effect of bulb shape, and a hundred and one other matters which were essential and which played such an important part in the progress of that industry. Day after day and week after week this type of research work was being done in the laboratories of the British electricity companies; and it was this work which had paved the pathway of progress in the electricity industry. He ventured to say that the gas industry, in spite of the good work done by its various societies, was not in such a fortunate position. For example, research in gas mantles was in the main left to the manufacturers, who did not regard their work with the broad outlook necessary for full efficiency from the gas industry's point of view. The same thing applied to the efficiency of fires, and so on; and he very much regretted the imperfection of this position. One of the experiments which the visitors had been able to see was concerned with particles of dust and their effect on a gas burner. To this end a balloon had been used effectively. They might ask: Why bother about dust? Well, it was by no means uncommon to find that small craters of dust particles had grown round the little holes in the burner injector; and in course of time these prevented the proper flow of gas, and reduced its momentum and pressure. The experiments carried out by Dr. Thomas had enabled them so to modify the construction of their burners as to minimize the chance of dust blocking-up the injector. Another point he would mention was the production of a tar suitable for use on roads. They had determined the characteristics of bitumen which were alleged to make this material particularly suitable for road surfacing, and these, if further experience showed them to be desirable, could be reproduced in the coal tar product. One of the major difficulties experienced was that roads were often treated with tar in a very unscientific manner. Then they had to deal with the prejudices of the public on the question of the pollution of streams as a result of using tar on roads. The South Metropolitan Gas Company were producing a tar which had not the toxic effect on fish which ordinary tar had. He would also refer to the important question of modern methods of gauging the different parts of appliances, to ensure accurate interchangeability. It was still quite a common experience to have deliveries of pipe of one stated diameter in which the different threads had not the same diameter. Standardization of plugs, taps, &c., had to be done in a more satisfactory manner. In regard to wrought-iron and steel barrel, it was a fact that in some parcels they found 75 p.ct. of steel and 25 p.ct. of wrought-iron pipes; and the number of pipes rejected in twelve months was enormous. They were endeavouring to instal only wrought-iron barrel for both external and internal services, for it was, he thought, generally recognized that wrought iron was preferable to steel. There was much to be done to perfect the efficiency of gas supply. To mention another thing, all appliances should have accurately fitting and gas-tight taps. The South Metropolitan Company had set themselves definite standards of mechanism, manufacture, and accuracy. On behalf of the staff and himself, he thanked them most sincerely for their expression of appreciation.

Motor coaches were in readiness to convey the visitors back to Westminster; and on all sides one heard expressions of appreciation of an afternoon well spent. Once again the South Metropolitan Gas Company had given expression to their underlying motive—progress through efficiency. Memories of the highly interesting visit will not be readily effaced.

Electrical Manufacture of Carbon Black.

Indicating the lines of suggested improved apparatus for making carbon black from gas oil, kerosene, or other liquid hydrocarbons, Mr. J. J. Jakosky, of the United States Bureau of Mines, says, in Technical Paper, No. 351, that the oil would be placed in a suitable storage tank, and then pumped to counter-current gas scrubbers. From the header the oil would flow down through the scrubbers into the treating chamber. After passing through the arc or treating chamber, the treated oil would flow to a settling tank. In the settling tank the clear oil would gradually rise to the top, and pass out through an overflow, either back to the original storage tank or to stills for re-distillation. The carbon from the settling tank could be drawn out near the bottom, in the form of a sludge, and then treated. The gas produced during the decomposition of the oil in the arc chamber would be passed through the scrubber, counter-current to the incoming oil, and out of the gas outlet at the top of the header. This gas coming from the arc chamber contains a large amount of carbon in suspension; and it was found that thorough scrubbing was necessary in order to remove it. In order to aid the scrubbing process, it might be beneficial to have the entire system under pressure, in which case the pressure valve at the top of the header could be adjusted. The effects of pressure upon the carbon formation are not known; but to Mr. Jakosky it seems probable that a high pressure would tend to keep the oil in closer contact with the arc, prevent much volatilization of the oil, and thereby ensure higher efficiency. For manufacturing carbon black by the process described, the main essentials are cheap electric power and cheap light-oil distillates.

Fire at a Meter Works.—Damage estimated at several thousands of pounds has been caused by a fire at the works of Messrs. George Wilson Gas-Meters, Ltd., in Foleshill Road, Coventry. Three departments were gutted, and some damage was done to other portions of the premises and stock; but owing to the prompt work of the employees and the city fire brigade, the main building was saved. The cause of the outbreak has not been ascertained; but it is supposed to have been due to the heat of the sun acting upon the contents (straw and similar material) of a corrugated iron packing shed, situated on land adjoining the factory. At any rate, it was here that the conflagration originated.

Luton Gas Company Shares.—Last week Messrs. Cumberland & Sons, Auctioneers, offered at Luton 2000 new ordinary shares, class F, of £10 each, for sale on behalf of the Luton Gas Company, and described them as the "only local gilt-edged security." The standard dividend on these shares is 5 p.ct. per annum, but they are on a sliding-scale dependent on the price of gas, and for the past two-and-a-half years the dividend has been 8¼ p.ct. This new issue is made to provide capital for extensions of the undertaking, which has increased its output by more than 100 p.ct. in 18 years. The shares were offered in lots of two, five, and ten; each buyer of a lot having the option of taking the four following lots. A number of the earlier lots were sold at £13, but as the sale proceeded the price fell successively to £12 17s. 6d., £12 12s. 6d., and £12, which then became the standard. When the sale was adjourned, more than half the issue had been disposed of, and further sales at the £12 figure have since been made privately.

THE GAS EXHIBIT AT WEMBLEY.

THE WEMBLEY CLUB ROOM OF THE SOCIETY OF WOMEN JOURNALISTS IN THE ADMINISTRATIVE OFFICES OF THE GAS EXHIBIT.

The room is placed at the disposal of the Society by the Gas Exhibit Committee as a club room and meeting place for members and their friends, both from England and from the Overseas Dominions, during the run of the Exhibition. The panelling and furnishing of the room has been carried out by Messrs. Osborne & Co., of Grafton Street.

MODEL DOMESTIC LAUNDRY IN THE GAS EXHIBIT AT WEMBLEY.

The laundry is suitable for a large house or small hotel, and is equipped with gas-heated hot water circulator, supplying the sink, low-pressure domestic gas-irons, a high-pressure gas-iron, a high-pressure "Gladiron," and a gas-heated drying cabinet.

Possibilities in Bye-Product Recovery.

Selecting some of the bye-products of coke-oven practice which appeared to him to hold out the greatest promise of successful exploitation, Mr. R. L. Robinson, in a paper before the Northern Section of the Coke-Oven Managers' Association, referred to tetra- and deca-hydronaphthalenes, which are prepared by the combination of highly-purified naphthalene and hydrogen, under pressure and at a temperature of 200° C., in the presence of a suitable catalyst. Two hydrocarbons—known technically as tetralin and dekalin—have obtained a considerable degree of importance in Germany; and a special plant for their manufacture has been erected at Rodleban, with a capacity of 120 tons per day. They are both mobile, colourless liquids, and have found extensive use as turpentine substitutes, as solvents and chemical cleansers, for new dye intermediates, and as motor fuels. Their greatest claim, however, according to the author, is as turpentine substitutes. They have been used with much success in Germany in the manufacture of paints and varnishes, although it is said that they did not give an altogether satisfactory result with white paint and enamels. In connection with these two compounds, it was pointed out in the paper that the world's output of turpentine is 30 million gallons annually, three-fourths of which comes from the United States. The demand generally keeps pace with the supply, and this being the case, there should be a ready market for efficient substitutes.

CENTENARY OF BENZENE.

Faraday's Discovery.

There was celebrated yesterday, by a series of imposing functions, the centenary of the discovery of benzene by Faraday in the laboratory of the Royal Institution, where he worked for fifty years. In the morning appreciations of Faraday were delivered at a reception held by the President and members of the Royal Institution, in association with the Chemical Society, the Society of Chemical Industry, and the Association of British Chemical Manufacturers; and in the evening there was a banquet.

The "Daily Telegraph," referring in advance to the matter, said: "Not since the Royal Institution celebrated the centenary of Faraday's birth in 1891 have the members called together a more notable gathering of world scientists; for there will be some hundreds of guests famous in the world of chemistry and the innumerable allied chemical industries. As Prof. Armstrong said at an at-home held at the Institution: 'No single subject known to chemists has had such a vast progeny of useful bye-products as benzene—as we chemists call it—or benzole as the public and motorists in particular call it. It is really the hub of the chemical dyestuff universe, which has been responsible for setting scores of chemists and investigators developing Faraday's discovery and its application to a great variety of commercial uses. It is not too much to say that since 1870 two-thirds of organic chemical research has been devoted to the study of benzene and its derivatives. Faraday, as all students know, started work here as the assistant to Davy, and succeeded him. He worked here in the laboratory continuously for some fifty years; and the very first specimen of benzene made by Faraday and labelled by him is to be seen here. Faraday had been interested in the subject from 1818 onward; but it was not until June 16, 1825, that he communicated his discovery to the Royal Society. It was, indeed, an epoch-making discovery, and Faraday lived long enough to see the production of the first aniline colour, and to foresee, no doubt, something of the enormous development that would follow his discovery. But he himself, having made his fundamental discovery, like an artist, turned in search of new worlds to conquer, and applied himself to research in electricity, in which sphere his wonderful investigations rather overshadow his earlier experiments in the production of benzene.'"

Fish Drying by Gas.

The drying and smoking of fish has, according to Mr. Joseph W. Piatt, of the Brooklyn Union Gas Company, become an important industry in that city, and now engages the entire attention of several large firms—among the foremost of whom are Messrs. Oxenberg Bros., whose plant is illustrated in the "Gas Age Record." The plant, it appears, was built in 1924 for the exclusive purpose of smoking and handling fish. It is one of the largest and most modern plants for this purpose in the United States. It contains two large smoke-houses for drying and smoking salmon, and twelve small smoke-houses for the other varieties of smoked fish. Each of these smoke-houses is equipped with gas burners. Gas is the fuel used, because of the ease with which the work is done, and the better quality it gives to the products. This installation has a capacity of 250,000 lbs. of smoked fish per week, and an increasing business is demanding an enlargement of the plant facilities in the near future. The firm are enthusiastic believers in gas as the most excellent of fuels for use in their work. Gas for drying, and wood chips and shavings for smoking are the only fuels used in this plant to-day.

Gas Favoured in Brass Foundry.

It is stated by the "American Gas Journal" that a Rhode Island foundry which used to throw away 25 p.ct. of its expensive brass and bronze castings because they proved defective when tested, changed its fuel from coal to gas. Its rejections dropped to only 3 p.ct., and at the same time operating costs were reduced and the working conditions for the men greatly improved. The firm had tried every process they could discover with coal as the fuel; but although there were certain advantages, they could not get away from the fatally high percentage of defectives. Extensive experiments were made with coke and oil; but they were not materially better. When gas was tried, the firm specified that "it must reproduce the ideal conditions of melting with coal, but have none of the objectionable features." The gas "made good." It was found that with gas a desired temperature or furnace state could be reached at will, regardless of atmospheric conditions, and that this could be reproduced exactly for batch after batch of the alloys. The gas eliminated the labour of building fires hours before the start of the work, cleaning the fires, carrying out ashes, and handling new fuel. It also did away with the smoke, dirt, and terrific heat around the furnaces, which prevented the "melter" from giving his best attention to the work. The men liked this change so much that they did more and better work.

CORRESPONDENCE.

[We are not responsible for opinions expressed by Correspondents.]

Economics of Gas Production on the Therm Basis.

Sir,—Owing to unavoidable delays, many members were unable to obtain advance copies of my paper read before the Institution on Thursday, and I find several were anxious to take part in the discussion and have further points explained, but were prevented from doing so owing to their inability to obtain advance copies and the shortness of time available for discussion.

I was able to deal with one or two queries after the meeting, and I shall be happy to answer any further points by correspondence with individual members.

I take this opportunity of writing because, after the paper, one member (whose name I have forgotten) spoke to me near the platform, and I requested him to wait a minute or so, to enable me to deal with another matter. Unfortunately I was detained much longer than the time indicated, and when I returned the particular member had gone.

George Evetts.

REGISTER OF PATENTS.

Gas-Heated Bakers' Ovens.—No. 233,054.

Vicars, E. L., of Earlestown.

No. 2806; Feb. 4, 1924.

This invention relates to gas ovens for baking bread, biscuits, &c. In the type of oven wherein the goods are transported on chains, it has been found that, owing to the chain and to the channel supports for the chain being interposed between the lower burners in the oven and the trays supporting the goods, the bottom surface of the article to be baked at those points above the chains is not coloured to the same degree as the other portions. It has previously been proposed to interpose baffles, which may be perforated, between the burners and the goods in order to maintain a substantially constant temperature in the oven.

The oven of the present invention has a complete perforated floor which comprises chain rails for supporting a conveyor and baffle plates situated between successive chain rails and between the outside rails and the side walls of the oven.

The baffle plates are dished, with their upper edges meeting the upper edges of the rail channels; and the perforations are so graded as to give a preferential path through the channels to the hot combustion products.

Coke Separator.—No. 233,200.

Rigby, J., of Hackney, N. 1.

No. 16,908; July 15, 1924.

This invention is for a type of coke separator working on the flotation principle.

According to the invention the apparatus comprises a water tank divided into upper and lower communicating compartments, a rotary conveyor in the form of a bucket wheel rotating in the upper compartment, and an endless chain bucket conveyor operating in the lower compartment. The upper compartment is also provided with a chute to discharge the material from the bucket wheel outside the tank; the chain conveyor also discharging outside the tank.

In operation, the mixture to be separated is fed into the upper compartment on to a slotted plate beneath the bucket wheel. The heavier clinker falls into the lower compartment, while the coke floats and is picked up by the bucket wheel and discharged on to the chute. The clinker is removed from the lower compartment by the chain conveyor and discharged.

The churning of the water by the bucket wheel assists in the flotation of the coke; but if the coke is of such a nature that it does not float, coal may be fed into the upper compartment, and cutters attached to the bucket wheel churn up the clay, increasing the density of the liquid. The buckets on both convevors are perforated; and the material may be fed in through a rotary sieve. Suitable gearing is provided for driving the apparatus by hand or power.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.

The Standing Orders not previously inquired into which are applicable to the following Bills have been complied with: Blackpool Improvement, Oldham Corporation, and Uckfield Gas and Electricity.

The Bath Gas Light and Coke Company have withdrawn their petition against the Bath Corporation Bill.

European Gas Company, Ltd.—The Directors have, subject to audit, decided to recommend the payment, on Aug. 1 next, of a final dividend of 6s. per share, free of income-tax, which, with the interim dividend paid on Jan. 31 last, represents a total dividend of 5 p.ct., free of income-tax, for the year ended March 31. For the year 1923-24, a dividend of 4 p.ct., free of income-tax, was paid.

LEGAL INTELLIGENCE.

DEUCHAR v. THE GAS LIGHT AND COKE COMPANY.

HOUSE OF LORDS.—Thursday, June 11.

(*Before Viscount* CAVE (*Lord Chancellor*), *Lord* DUNEDIN, *Lord* ATKINSON, *Lord* SUMNER, and *Lord* BUCKMASTER.)

The appeal of Mr. John Lindsay Deuchar against the dismissal of his application for an injunction to restrain the Gas Light and Coke Company from manufacturing their own caustic soda for the purpose of working up residuals was considered by the Lords of Appeal on Thursday, June 11. Their Lordships, without hearing Counsel for the Gas Company, were unanimous in their decision to dismiss the appeal. (The proceedings in the High Court and in the Court of Appeal were reported in the "JOURNAL" for Jan. 23, 1924, p. 210; May 28, 1924, p. 611; and June 25, 1924, p. 911.)

Appellant was represented at the House of Lords by Mr. A. C. CLAUSON, K.C., Mr. DIGHTON POLLOCK, and Mr. J. L. MURPHY. Respondents were represented by Sir JOHN SIMON, K.C., Mr. W. A. GREEN, and Mr. A. ANDREWES UTHWATT.

Mr. A. C. CLAUSON, K.C., opening for the appellant (who is Secretary of the Castner Kellner Alkali Company, Ltd.), said that, as a holder of a small sum of stock in the Gas Light and Coke Company, he was bringing an action against them with a view to testing the limits of the powers of the Company. Though the action was brought by the appellant as a holder of stock in the Company, Counsel said that he did not wish for a moment to conceal the fact that the action was brought in the interests of certain traders, who took the view, rightly or wrongly, that the Company were exercising certain activities which they were not authorized to exercise. The question to be decided was purely a matter of the construction of the Acts which regulated the Company. The facts, in substance, were not in dispute. The Company had erected a factory for the manufacture by the electrolytic process of caustic soda required for the purpose of treating their naphthalene, and the erection of that factory was not within the powers of the Company. Counsel went on to explain that the caustic soda was to be used for converting naphthalene into beta-naphthol, and that the manufacture of caustic soda by the electrolytic process produced chlorine as a bye-product. Neither caustic soda nor chlorine was a residual of gas. The chlorine was got rid of by turning it into bleaching powder, which latter the Company sold. Counsel pointed out that with caustic soda and chlorine one could make an enormous number of saleable combinations.

Counsel then quoted at length from the evidence given in the lower Courts with regard to the manufacture and uses of caustic soda and chlorine.

Lord BUCKMASTER, having obtained the admission from Counsel that the Company were competent, within their Charter, to convert naphthalene into beta-naphthol, said he understood the appellant's case was that they must not produce the caustic soda for that purpose, but must buy it elsewhere. He pointed out that the Company had not sold the caustic soda they had made.

Mr. CLAUSON said his case was that the Company could not manufacture it.

The LORD CHANCELLOR said that, assuming the Company were entitled to manufacture caustic soda for treating residuals, they could not do this without incidentally producing chlorine. There was no evidence to show that the chlorine had been used for treating other residuals, but there was evidence that it might be so used. Assuming they did not use it for treating other residuals, could they not produce it?

COUNSEL replied that what the Company did was to get rid of the chlorine by setting-up another plant, and producing another thing altogether.

The LORD CHANCELLOR pointed out that they must get rid of the chlorine.

COUNSEL said his argument would be based on the fact that the Company were given express powers to manufacture various things, but none of the things included caustic soda.

Coming to the relevant sections of the Company's Acts, Counsel dealt first with section 40 of the Act of 1868, which stated that the Company may "make and store and supply gas, and may convert, manufacture, and deal with, sell, or dispose of, coke, tar, coal, pitch, asphaltum, ammoniacal liquor, oil, and all other products, refuse, or residuum arising, remaining, produced by, or obtained from, the making by them of gas, or the materials used therein, and may make and sell all articles produced from, or by means of, those several matters, . . ." His contention was that there was nothing there that could possibly be suggested as authorizing the manufacture of caustic soda.

Lord BUCKMASTER said there was nothing which expressly conferred upon the Company the right to manufacture the reagent used for the conversion of naphthalene into beta-naphthol, but whether or not it was implied was a matter to be determined.

COUNSEL's submission on Clause 40 of the 1868 Act was that it was a very strong line to seek to find in that clause, by implication, a power to manufacture something which was not named.

Lord ATKINSON said there was no power for the Company to manufacture electricity, but yet it might be a reagent for dealing with residuals.

COUNSEL replied that, as a matter of fact, the Company did generate their own electric power.

Lord ATKINSON asked whether the argument would not be the same in that case.

COUNSEL said he was by no means prepared to say that it was within the power of the Company to generate electric power.

Lord BUCKMASTER pointed out that the object of the Statute was to give the Company limited powers of trading. Was it not also to enable them to do all things necessary for the purpose of efficiently carrying on that trade?

COUNSEL said it was.

Lord BUCKMASTER asked why, if it were necessary for the efficient carrying on of the trade that they should provide themselves with this reagent cheaply, instead of buying it from outside, the Company should not do it. If they were selling caustic soda outside, it would be quite a different proposition, but they were providing it for the purpose of their undertaking.

COUNSEL replied that their Lordships were basing the power to manufacture caustic soda on something which was implied by reason of the power given to carry on another process in the most advantageous and satisfactory way. The point was that, if they could get it perfectly well without manufacturing, why manufacture it, when their powers of manufacture were expressly limited?

Lord BUCKMASTER, in the course of discussion, said it was not unlikely that what the legislature meant was this. Having given the Company power to make gas, unless they also gave power to manufacture things necessarily resulting from the manufacture, the Company would not be able to make the gas. Therefore, they had given the Company power to make things resulting from the manufacture of gas. The Company could convert and make, deal with and sell, all those products arising from the making of gas, as mentioned in Clause 40 of the 1868 Act, and could make and sell all articles produced from, or by means of, those several matters. This must mean something more than the making and selling of the things which were mentioned, and, therefore, it must mean that they might make and sell all the things necessary for the conversion of those products.

JUDGMENT DELIVERED.

Judgment was delivered in favour of the Gas Company without their Counsel being called upon to respond to the arguments put forward on behalf of the appellant.

The LORD CHANCELLOR, in his judgment, said that, notwithstanding the careful and complete argument addressed to their Lordships on behalf of the appellant, he did not feel any doubt as to the correctness of the decision of the Court of Appeal in this case. The respondent Company, the Gas Light and Coke Company, was formed by Statute for the purpose of making and selling gas; and in the course of making gas from coal, the Company necessarily produced a number of residual products. It was obviously undesirable that these residuals should be wasted if they could be so dealt with as to acquire a money value, and it was not disputed that the Statutes under which the respondents acted authorized them to convert these residuals into a marketable state. In a reference to the production of naphthalene and its conversion to beta-naphthol, he said the conversion was best effected by the use of caustic soda, and the respondents did convert their naphthalene into beta-naphthol in that way. For a time they had provided the necessary caustic soda by purchase, but recently they had commenced, presumably for purposes of economy, to manufacture it themselves. It appeared from the evidence that the respondents only produced in this way so much caustic soda as was required for the purpose of converting their naphthalene into beta-naphthol, and that they only used caustic soda produced by themselves for this purpose. Chlorine could be used for converting other residuals; but it did not appear upon the evidence that chlorine, which was a bye-product of the manufacture of caustic soda by the respondents, was used only for that purpose. It appeared that at all events some of the chlorine had been converted to another purpose, and was so used. The appellant was the Secretary of another Company which apparently dealt in caustic soda, but, being qualified for the purpose of bringing this action by the purchase of shares or stock in the respondent Company, he had taken the objection that the latter Company had no power under their Statutes to manufacture caustic soda, even for use in converting their naphthalene into beta-naphthol; and he had brought this action claiming an injunction to restrain them from making caustic soda. The action was dismissed by Mr. Justice Astbury, and the decision stood confirmed by the Court of Appeal. There was no dispute as to the legal propositions which were to be applied in this case. It was enough to refer to the rule as laid down by Lord Watson in the case of *Baroness Wenlock v. the River Dee Company*, when he had said: "Whenever a corporation is created by Act of Parliament, with reference to the purposes of the Act, and solely with a view to carrying those purposes into execution, I am of opinion not only that the objects which the corporation may legitimately pursue must be ascertained from the Act itself, but that the powers which the corporation may lawfully use in furtherance of those objects must either be expressly conferred or derived by reasonable implication from its provisions." To this statement, the Lord Chancellor added a sentence from the speech of Lord Selborne, in the case of the *Attorney-General v. the Great Eastern Railway Company*, in which he had said: "I agree with Lord Justice James that this doctrine of *ultra vires* ought to be reasonably, and not unreasonably, understood and applied, and that whatever may fairly be regarded as incidental to, or consequential upon, those things which the Legislature has authorized ought not (unless expressly prohibited) to be held, by judicial construction, to be *ultra vires*."

With these statements of law in mind, the Lord Chancellor turned to the Statutes of the Gas Light and Coke Company. The first material section was section 40 of the Company's Act of 1868 (part of which he read). Applying that section to the particular facts of this case, it appeared to him to result in this, that the Company might convert and deal with naphthalene. In other words, they might treat naphthalene by converting it into some other marketable product. It was plain that, for the purpose of so converting naphthalene in the best way, they must have caustic soda, and accordingly the provision of caustic soda was incidental to the conversion of naphthalene. The only point was whether this caustic soda must needs be provided by the method of purchase, or whether it was in the power of the Company as incidental to their powers to convert, themselves to manufacture caustic soda. If that section stood alone, it would appear to him to be reasonably plain, on the facts of the case, that the manufacture of caustic soda was incidental to the process of con-

version of naphthalene into beta-naphthol, or, in other words, that the manufacture of caustic soda was a part of the process of conversion.

But the Statutes did not stop there; and His Lordship went on to deal with section 43 of the same Act. He considered that the section, properly read, did authorize the Company to convert its naphthalene into beta-naphthol, and to provide the necessary materials for that purpose. Again, under that section, he saw no reason why the materials should not be provided by the process of manufacture, or why they should only be provided by the process of purchase.

After quoting the other relevant sections of the Company's Acts, His Lordship said that, if it could be suggested that the Company in this case were engaged in manufacturing caustic soda for the purpose of sale, the result might be very different; but he considered it was plain from the evidence that they were doing no such thing, and that they were making caustic soda only for the purpose of using it in the process of converting one of their residuals into a marketable product.

As regards chlorine, this appeared to be a small matter. Chlorine was not made for the sake of making chlorine; it was a necessary bye-product evolved in the process of making the caustic soda. Chlorine might be, and possibly would be, used for converting some residuals into something which could be sold, but, in any case, it must be got rid of by the Company; and he did not think the plaintiff had said, in his pleadings, that it was the fact that the Company, in that respect, were going beyond their powers.

In summing-up the case, His Lordship adopted the statement by Lord Justice Warrington in his judgment on the present case in the Court of Appeal, when he had said: "My view in reference to the facts of this case may be thus summed-up. The defendant Company have express powers to convert naphthalene into beta-naphthol; they have by reasonable implication a power to provide the proper reagent for that purpose—namely, caustic soda—a proper and reasonable means of providing that substance is to make it, and, to do so not being excluded, they have by reasonable implication the power to provide the substance by that means."

Therefore, the Lord Chancellor moved that the appeal be dismissed, with costs.

Lord DUNEDIN said he had not felt any doubt that the decision of the Court of Appeal was right. Their Lordships had been favoured with a very careful and minute analysis of the various Statutes which applied to the Company. Speaking for himself, he did not think the case was much helped by, or depended on, such analysis. He looked upon such Statutes as merely exegetical of the leading Statutes, and section 40 of the Act of 1868, in ordinary and non-technical language, seemed to him very clearly to authorize the Company to put the residual products into such a shape as to make them commercially valuable. Then they had to see whether what was done fell within the dictum of Lord Watson which had been quoted by the Lord Chancellor. The Company must have reagents for dealing with those residual products; and he could not see that there was really any difference between buying the reagents and providing them by manufacture in their own works. At the same time, if a case had been made out that, under cover of doing something incidental to the proper exploitation of waste products, the respondents were really entering the market as producers of some product not itself a residual product, and thereby really becoming manufacturers of some other articles than those which they were allowed to manufacture under their Statutes, they might, he considered, have been restrained. But no such case had been made; and he considered the appeal failed.

Lord ATKINSON said he thought the judgment in the Court of Appeal was right, for the reasons given in the separate judgments there.

Lord SUMNER and Lord BUCKMASTER concurred.

The appeal was formally dismissed, with costs.

Mr. Arthur Sainsbury, Secretary to Messrs. Ewart & Son, Ltd., notifies shareholders that his Directors have declared a dividend for the half-year ending June 30, 1925, on the preference shares at the rate of 16 p.ct. per annum, and an interim dividend on the ordinary shares at the rate of 32 p.ct. per annum (or 16 p.ct. for the full year), both subject to income-tax. These dividends are at the same rate as those paid on June 30, 1924, in respect of the first six months of last year. Arrangements have been made with the Liquidator of Messrs. Ewart & Collis, Ltd., for the transfer before June 30 of the shares now held by him in Messrs. Ewart & Son to the shareholders in Messrs. Ewart & Collis, in order that they, as shareholders in Messrs. Ewart & Son, may receive the dividends on the preference and ordinary shares payable upon that date.

MISCELLANEOUS NEWS.

GAS REGULATION ACT APPLICATIONS.

The following notices have appeared in the "London Gazette" regarding applications to the Board of Trade under the Act.

SPECIAL ORDERS.

Chapel Whaley and District Gas Company.

The Company intend to apply for an Order under section 10, to enable them to use for gas-works purposes scheduled land, to raise additional capital, and to make provisions regulating the supply of gas.

Solihull Gas Company.

The Company notify their intention of applying to the Board of Trade for an Order under section 10 to enable them to acquire additional land, to raise additional capital, and for other purposes.

BIRMINGHAM GAS DEPARTMENT.

The Birmingham Gas Committee, in their report to the City Council, recommend that the prices of gas be increased as from the June readings of the meters, for lighting and domestic purposes, up to and including 100,000 c.ft., from 2s. 10d. per 1000 c.ft. to 3s. 2d. The percentage increase of the suggested price over Midsummer, 1915, is 58·33. Other prices are also raised.

The Committee, in an explanation for the increase, point out that in June last year they commented on the reductions in price which had been made during the preceding twelve months, and drew attention to the fact that residual products were then showing signs of weakening, and that there had been a considerable fall in the value of tar products. This made the position one of much anxiety, as there was very little margin in the existing scale of charges. Unfortunately there had been a continued slump in residual products, which had so adversely affected the finances of the Department as to make it necessary to increase the price of gas. The fall in the revenue from tar during the year was nearly £70,000, notwithstanding that a larger quantity was produced in the year ended March, 1925; and it was interesting to note that, if values had been maintained at the level of the previous year, additional revenue to the extent of £94,757 would have been provided. After taking into account the increased quantity of ammoniacal liquor made and sold during the year, the fall in value of this residual has resulted in a loss of revenue equal to £21,644. A reduction of 5s. per ton had to be made recently in the price of coke, owing to the increasing stocks and the general reductions in price made by other gas undertakings, which made it very difficult to obtain sufficient orders to keep the yards clear of this product. That reduction represented a loss of income of £100,000 per annum. An amount of £60,000 should have been allocated to Nechells Works reconstruction in accordance with the arrangement made with the Finance Committee; but, owing to financial stringency, this could not be done. Provision must, however, be made for resumption of the annual payment in the current year.

As to the annual accounts, the Committee state that they show a deficiency of £78,518, which amount has been transferred from the reserve fund. The expenditure for the year amounted to £2,226,764, a decrease of £117,023, but credit had been taken for an abatement of income-tax on replacement of plant amounting to £63,555. That item would not recur in future years.

The Unemployment Relief Schemes which have been adopted by the Council had involved the Committee in heavy expenditure in altering the position of, and rearranging, gas mains in the thoroughfares which had been improved and reconstructed. The expenditure under this head amounted to £58,733. During the year, 810,110 tons of coal were carbonized—an increase of 10,951 tons over the previous year. In addition 1,734,723 gallons of oil were used in making carburetted water gas. The gas sold amounted to 12,659 million c.ft., the largest quantity sold in any year in the history of the undertaking, and an increase of 5·35 p.ct. over the quantity sold in the preceding year. The increase was no less than 642¼ million c.ft.; and of this quantity approximately 358¾ millions were due to increased demands for lighting and domestic purposes. The average net price realized per 1000 c.ft. during the year was 2s. 5·47d., as against 2s. 9·77d. in the year ended March, 1924.

The two concrete gasholder tanks at the Washwood Heath Works had been satisfactorily completed, and considerable progress had been made with the erection of the holders and framework. One holder would be completed in August next, and the other towards the end of the year. It had become necessary to carry out extensive repairs to 22 beds of vertical retorts at the Windsor Street Works, which had been in operation continuously for five years. The repairs would be carried out during the coming summer when the plant could be let down without inconvenience, owing to the smaller demand for gas. The cost would be approximately £38,000.

Extensions of Gas Mains at Stafford.—At a recent meeting of the Stafford Town Council, the Gas Committee recommended that a 12-in. main be laid along the Wolverhampton Road from Park House to the junction of Burton Lane, a distance of 403 yards, and a 10-in. main along Burton Lane for a distance of 416 yards, at an estimated cost of £1800. The recommendation was carried.

Progress at Ashbourne.—At the monthly meeting of the Urban Council, a report on the gas undertaking for the year ended March 31 last was received, showing a gross profit of £3613. After meeting loan charges, &c., a net profit of £94 remained. The make of gas had increased by 2,572,700 c.ft. to 49,000,000 c.ft. for the year. In view of the anticipated saving in the cost of coal during the current year, it was decided to reduce the price of gas by increasing the discounts to ordinary consumers, but the exact amount of discount could not be fixed until the coal contracts were settled.

SOUTHAMPTON GAS ORDER.

Mr. H. C. HONEY (Director of Gas Administration at the Board of Trade) inquired into an application by the Southampton Gaslight and Coke Company for a Special Order under section 10 of the Gas Regulation Act, on Monday, June 8, at the offices of the Board. The purposes of the Order are to extend the area of supply of the Gas Company and to authorize new provisions with regard to capital and borrowing powers. There are also a number of miscellaneous provisions. The new area which is to be added to the Gas Company's existing area of supply consists of the parishes of Dibden, Marshwood, and Fawley, and the parishes of Bursledon, Botley, and Hedge End. With regard to dividends, a clause in the Order provides that the limitation of dividends to 5 p.ct. per annum on the ordinary capital and 4 p.ct. per annum on the preference capital, which was imposed on capital issued under the Company's Act of 1906, is not to apply to the capital issued after the date of the Order, but the Company are not to pay a dividend larger than 6 p.ct. on such capital, unless a larger dividend is necessary on the ordinary capital to make up the deficiency of any previous dividend. The Company, however, are not to make up a deficiency in any previous dividend after five years from the date when such previous dividend was paid or payable. Borrowing powers are sought by the Company up to one-half of the amount of the paid-up capital. Powers are also sought to issue debenture stock; and the interest on that debenture stock, or on any money borrowed under this Order, is not to be more than 6 p.ct. Powers are also contained in the Order to grant pensions and to adopt a co-partnership scheme.

Originally there were three sets of objections to the provisions of the Order. The first was by the Bursledon Bridge and Roads Company, who asked for protection in respect of the laying of gas mains over Bursledon Bridge and along roads which are owned and maintained by the Bridge Company. The opposition was withdrawn, however, on the insertion of an agreed clause. Another set of objections was raised by the Southampton Corporation; but certain amendments to the Order were agreed between the Gas Company and the Corporation. The third series of objections came from the Southern Railway Company, who asked for protective provisions.

The Railway Company were represented by Mr. W. BISHOP (Solicitor to the Railway Company); and Mr. C. F. BAKER (Messrs. Bircham & Co., Parliamentary Agents) represented the Gas Company.

Mr. BAKER, dealing with the Railway Company's objections, said that one of these related to a clause giving the Gas Company power to lay pipes for ancillary purposes, but a proviso had been added to the effect that the Company were not to lay such mains under any railway of the Southern Railway Company without their consent. The proviso also states that such mains may only be laid in certain specified streets in the borough of Southampton, and then only with the consent of the Corporation.

Another objection by the Railway Company which was disposed of by agreement had reference to the clause relieving the Gas Company of the obligation to supply gas for other than lighting and domestic purposes from mains of insufficient capacity. The Company deleted the clause in the original Order, and inserted in its place the clause recently agreed between the National Gas Council and the Railway Companies, and which has come to be known as the "Pinner" clause. [This clause was inserted recently in the Mansfield Corporation Bill, and is set out in the "JOURNAL" for June 3, p. 677.]

The outstanding objections of the Southern Railway Company arose in connection with a clause which they asked should be inserted in order to protect their interests. Mr. Baker said that the Gas Company were prepared to give a certain measure of protection, and that would be agreed. The Railway Company contended that the provisions of the Gas Works (Clauses) Act, 1847, did not afford adequate protection for their roads, bridges, level crossings, and other works, and asked for special protection. The Gas Company, on the other hand, disagreed that the Act of 1847 did not afford adequate protection, and pointed out that the Gas Works (Clauses) Acts of 1847 and 1871, which were incorporated in their Acts and the present Order, had afforded adequate protection to the Railway Company in the past. If any alteration of the general law were necessary, it should be made by public legislation, and they objected to being placed in a position different from that of other gas undertakings, as the result of the insertion of special provisions in the present Order.

Mr. BISHOP said that the Railway Company were now asking for no more than they had been granted on many occasions. The clause which he now asked should be inserted in the present Order had been amended, and agreement had been reached between the parties, except in respect of two sub-clauses. The first of these related to the carrying of mains under railways by the Gas Company, and provided that the Gas Company should restore and make good, to the reasonable satisfaction of the Railway Company's engineer, the railways which might be disturbed or interfered with. The discussion arose on a proviso which it was proposed should be added, to the effect that, if the Engineer of the Railway Company should think it necessary in any case for the works of the Gas Company (other than the actual laying down of mains or pipes) to be executed or carried out by the Railway Company, such works might be carried out by the Railway Company, and the reasonable expense incurred by them should be repaid to them by the Gas Company.

It was pointed out by Mr. Bishop that the present case, so far as the Railway Company were concerned, was exceptional. A new railway was being built, the greater part of which was included within the proposed extended area of supply of the Gas Company. This line had been difficult to construct, owing to the nature of the subsoil and the waterlogged condition of the country. The Railway Company's Engineer feared that the maintenance of this line would be difficult for some time to come, and was afraid that work might be carried out by the Gas Company which would seriously jeopardize the Railway Company, and which might lead to the suspension of traffic. He wished to guard against this.

Mr. BAKER remarked that the Gas Company were anxious to do all they could to avoid difficulty.

Mr. *A. W. Salumper* (Chief Engineer to the Railway Company), in evidence, referred to a case in which works carried out by a county council had resulted in damage to the railway, which had had to be repaired at considerable expense. If the proviso asked for by his Company were inserted in the present Order, the Gas Company would not be put to any expense; on the contrary, the probability was that the Gas Company would be saved expense. After many years' experience, he had come to the conclusion that some such definite protection was needed by railway companies.

Mr. BAKER, in the course of discussion, said that if it were made clear that the works which the Railway Company were allowed to carry out were limited to supporting and protecting their railways, he did not think the Gas Company would object. The proviso in its present form would leave the Railway Company power to fill in a trench after a gas main was laid; but, if it were not filled in properly and the gas main fractured as a result, who would be responsible?

Further discussion then ensued in order to arrive at a suitable wording of the proviso in question, and finally Mr. Honey suggested that the parties should consult privately. His suggestion was adopted; and it was subsequently agreed that the Railway Company should have power, if their engineer thought necessary, to carry out the works of the Gas Company—other than the actual laying down of mains or pipes, "including the filling in and consolidating of the trench in which such mains or pipes are laid."

The other proposed sub-clause to which the Gas Company objected was one providing that, if any injury or damage to or interruption of traffic on the railways of the Railway Company arose in any way owing to the construction, existence, or failure of the works of the Gas Company, they should make full compensation to the Railway Company.

In the course of the discussion upon this, Mr. Bishop said he did not quite appreciate the Gas Company's reasons for objecting, because it was a provision which the railway companies had invariably obtained in the past.

Mr. HONEY asked to what extent this sub-clause was an extension of the general law.

Mr. BAKER said that at present the Gas Company were only liable in the case of damage caused through their negligence.

Further discussion of the matter ensued, and various forms of wording were considered. Finally, the Gas Company agreed to the insertion of the sub-clause, with the deletion of the word "existence." Thus, they are to be liable to make compensation to the Railway Company for injury or damage to or interruption of traffic arising owing to the "construction or failure" of the works of the Gas Company. Mr. Honey intimated that the Board of Trade would insert the sub-clause in this form.

This disposed of the opposition of the Railway Company.

Consideration was then given to a request by the Southampton Corporation that the charge for gas within the Borough should always be 2d. below the price charged outside. Mr. Baker said that the Gas Company were prepared to put in a provision to the effect that the charge within the Borough should always be less by 2 d. per therm than the highest price charged outside the Borough; but they could not possibly agree to a provision which might have the effect of making them charge considerably less than the amount they ought to charge in Southampton. On the outside fringe of the Borough they would not charge the maximum, but the lowest price they could charge, and it would not be fair to make the Company reduce the charge in the Borough accordingly. On the outside limits of supply, the Company were charging the full differential, whereas on the fringe of the Borough they were not.

Mr. HONEY said that the Southampton Gas Company's Act of 1898 contained a proviso that, if the prices were increased, the increase should be made uniformly over the whole of the limits. There was no provision, however, that reductions should be uniform. In effect, therefore, the Corporation were asking that if there were a difference at present between the prices in the Borough and the outside areas, that difference should be stereotyped for a time. He asked how the figure of 2d. was arrived at.

Mr. *J. R. H. Jacobs* (General Manager to the Company) said that was the figure given in the Company's Charges Order of 1921, where it was laid down that the maximum prices should be 16d. and 18d., in place of the maximum prices given in the Act of 1898—namely, 3s. 6d. and 4s. 6d. per 1000 c.ft.

Mr. HONEY said there was no differential mentioned in the 1898 Act, but two maximum prices, which could be dealt with independently so far as a reduction was concerned, but which must be dealt with alike so far as an increase was concerned.

Mr. *Jacobs* agreed.

Mr. HONEY said that, having regard to the practice of the Company in the past with regard to these differential prices, and to the fact that in 1898, when the maximum price in the outside districts was fixed, there was no provision that the Company were for a time to charge a higher price in the outside district than in the inner district, he was not disposed to recommend the Board of Trade to insert anything in the present Order. It seemed to him that what the Corporation were now asking the Board of Trade to do was not merely to affect the price in the new area, but to affect the price in all the districts now supplied by the Company outside the Borough, which latter were dealt with by the Act of 1898. Certainly, without hearing representatives of the outside districts, he would hesitate to put the Company under an obligation to charge a higher price in those districts for a time than was charged within the Borough. He considered that an important change of this kind ought not to be made without giving the people affected an opportunity of being heard.

Another matter discussed was a clause in the present Order giving the Company power to levy such charges as they thought fit for taking the reading of any meter fixed in a house, which was either in whole or in part let furnished at times other than those of the Company's

periodical readings. There was a proviso to this clause, to the effect that for each reading taken within the Borough as constituted at the date of the Order such charge should not exceed 1s. Mr. Honey asked why the maximum charge of 1s. should be confined to within the Borough. The reply was that this was due to the special circumstances of the Company. The area covered was a large one, and the offices were situated in Southampton. The fee should be kept as low as possible within the Borough, but it was considered reasonable that it should be higher at the extreme limits of the area. The probability was that in the immediate neighbourhood of the offices of the Company the charge would be less than 1s., and perhaps nothing at all. On the other hand, if a special reading were made on the extreme edge of the area, a man would have to travel about 14 miles each way for the purpose. Often the Company received notice at the last minute that a house was changing hands, and the outgoing tenants wanted the meter read and the account left the same day. This meant sending a man specially from the office to read the meter and collect the money.

Mr. HONEY intimated that the clause could be inserted as put forward.

The inquiry then closed.

SAFEGUARDING OF INDUSTRIES ACT.

Gas Mantle Inquiry.

(*Continued from p.* 749.)

Tuesday, June 9.

The Committee concluded their proceedings on Tuesday, June 9.

Herr *Heinrich Zeigler* re-entered the witness chair, and handed to the Committee copies of wages agreements into which his Company had entered recently. These had been asked for previously by the Chairman. A statement as to the taxes payable in Germany was also produced.

Witness was then cross-examined by Mr. Soper (for the applicants), whose object was to show that Herr Zeigler's Company was an amalgamation of a number of foreign mantle manufacturing concerns, and to emphasize that the opposition to the present application was in effect the opposition of foreign manufacturers, and was not representative of the general body of importers in this country. His questions were shortened, however, by an intimation from the Chairman (Sir Frederick Mills) that this was quite clear.

Witness made a correction to his previous evidence with regard to the cost of carriage, freight, and insurance from the German factory to the port of discharge in the United Kingdom. This he had said was 3s. per gross; the wholesale price in Germany was 3s. below the wholesale price here, so that he was sacrificing nothing by exporting to this country. He now said, however, that the cost of carriage, freight, and insurance was 2s.

With regard to prices in this country, witness agreed that during 1923 (when there was a duty on German mantles under Part II. of the old Safeguarding of Industries Act), his prices here were less than the prices operating at the present time. He admitted that those 1923 prices were based upon those ruling in this country, and not upon his production costs, the reason being that, owing to the inflation of German currency, he did not know what his production costs were. At present, however, prices were based on production costs, which he could ascertain because the German currency was stabilized. The stabilization took place about November, 1923; and although the low prices charged yielded his Company a profit before that time, they did not yield a profit after stabilization.

Asked what was the present price of standard German mantles in the United States, witness said he did not now export to that country, because the duty was too high.

This concluded the evidence on behalf of the importers who are opposing the application, and further evidence was called on behalf of the applicants.

Mr. *N. W. Buis* (who gave evidence on a previous occasion as to the rates of wages paid by mantle manufacturers in Poland) said he had been to Germany within the last fortnight, and had ascertained from a worker at the Auer Company's factory at Berlin the rates of wages paid there. These were considerably below the figures given by Herr Zeigler. He had also advertised for clerical workers, and the salaries asked for by those who had replied to his advertisement were also low.

Cross-examined by Mr. Macaskie (representing the importers) witness said that before leaving for Germany he had seen the figures which were to be given on behalf of the importers as representing the rates of wages paid by the Auer Company at Berlin. He had not tested these by putting them to his informant.

Mr. *C. S. Garland* (Managing Director of the Clay Ring Company, Ltd.) said that prior to the war the manufacture of clay rings in this country was in German hands, and he believed the business was in close association with the German gas mantle industry. In the early part of the war the factory (which was situated at Earlsfield, London) was taken over by the Custodian of Enemy Properties, and in 1917 the shares were sold under the Trading with the Enemy Act. Several British mantle manufacturers, feeling that it was necessary to remove this important source of raw material from any possibility of foreign control, had combined to purchase the shares of the business. The output of the factory had proved to be insufficient for the demand in 1917 and 1918, and two other factories were purchased—one at Nottingham, and the other at Ashby-de-la-Zouch, in Leicestershire. In 1920 all three factories were working, and the output of rings was over 60,000,000, the number of people employed being 520. The renewed importation of German mantles, however, had necessitated the closing of the two new factories, and the concentration of manufacture at Earlsfield, for the sake of economy. At the end of 1924 the workers employed there numbered 172. With the increased importation of German, Austrian, Italian, and Polish mantles in 1925, the output at the factory had been further reduced, and only 102 workers were now employed. There were only four manufacturers of these rings in the world, only one being in England. It was of the utmost importance to the British mantle manufacturers that the Earlsfield factory should be kept in operation, and that it should have a sufficient output to ensure its being able to compete on reasonable terms with the factories abroad. If output were reduced so that the Clay Ring Company could only sell at its present price at a loss, the British mantle manufacturers would either have to bear those losses, which would make them still less able to meet competition, or close the ring factory. In the latter case they would be entirely at the mercy of their German competitors for supplies of one of their essential raw materials, and one which, probably as much as thorium nitrate, was now a key to the mantle situation.

In February of this year, Mr. Garland had made inquiries as to the rates of wages paid in German mantle factories, and had obtained from three different sources figures which were substantially identical to those given by Mr. Talbot as the rates obtaining in Germany at that time. As to the reduction in the number of mantles consumed in this country now as compared with the period before the war, he attributed this to the change from the upright to the inverted type of mantle, and even more to the great improvement in quality of the inverted type.

Cross-examined, witness said that the price of mantle rings was not fixed by the mantle manufacturers; he fixed the price in relation to the cost of production.

Mr. *Edmund White* (Managing Director of Messrs. Hopkin & Williams (Travancore), Ltd., and of Messrs. Thorium, Ltd.) referred to the German control of the deposits of monazite sand (from which thorium nitrate was made) before the war, and said that when war broke out, thorium nitrate was not being commercially manufactured from monazite in this country. As soon as supplies were available, however, Messrs. Thorium, Ltd., commenced to produce thorium nitrate and cerium from monazite on a commercial basis. The manufacture of thorium in this country could not be safeguarded if gas mantles, which were virtually the only articles for which it was used, were allowed to come into this country with a duty calculated only upon the value of the thorium *qua* thorium contents of the mantle, and not upon the thorium in the form of gas mantles (including the cost of putting it in that form), or unless an effective duty were imposed upon the gas mantle itself. His was the only Company at present manufacturing thorium nitrate in this country. If demands for thorium nitrate from British gas mantle manufacturers were further curtailed by reason of foreign mantle competition, then either the price would have to be increased or the manufacture of thorium nitrate, and with it cerium and mesothorium, would cease, and again the country would have to look to foreign countries in times of peace and war for those essential materials the manufacture of which had been considered by all Governments as a key industry.

In cross-examination, witness said that 50 p.ct. of the capital of Thorium, Ltd., was owned by a gas mantle manufacturing company, and the remainder by other interests; but the price of thorium nitrate was not controlled by mantle manufacturers.

This concluded the evidence for the applicants.

Herr *Zeigler* was then re-called for cross-examination by Mr. Soper with regard to the rates of wages paid by his Company. Witness said that the rates paid to the mantle operatives were the same as those paid in the Company's chemical factory, but those rates were not paid in an electrical factory also owned by them. Witness could not say whether or not Mr. Soper was correct in suggesting that the wages paid in other mantle factories in Germany were only two-thirds of those paid by Herr Zeigler's company, or that the latter were the highest paid in any industry in Germany.

Mr. MACASKIE, summing up on behalf of the opponents, contended that the whole of the conditions laid down by the Board of Trade had to be satisfied by the applicants if they were to be successful, but that in only one particular had the applicants been able to satisfy those conditions. The industry was not of substantial importance from the point of view of the number of workers employed, or from the national point of view. In his comments in this connection, he said that from the standpoint of volume of employment the industry was miserably out of the picture. The real difficulty of the industry before the war, when there was a greater degree of competition than now, was not that the British industry could not cope with the demand, but that the supplies of monazite sand, from which thorium nitrate was obtained, were under foreign control. This did not apply now, however, and there was no reason to suppose that the industry would ever again be short of essential supplies. As to the suggestion that German mantles were being retained for consumption in this country in abnormal quantities, he met that by pointing out that before the war foreign manufacturers supplied 75 p.ct. of the home consumption of standard mantles, whereas in 1924 they had supplied only 36 p.ct. Also, 1920 should not be taken as a standard year in this connection, because foreign manufacturers had not had time to re-organize their competition then. In connection with this competition, Germany had not been breaking new ground, but was simply returning to a market which it had held up to 75 p.ct. of the consumption before the war. Commenting on the allegation that foreign mantles were being sold in this country at prices below which they could be profitably manufactured here, he said that, although costs of materials were about the same in this country and in Germany, and there was only a difference of 1d. per hour between the wages paid in the two countries, there was still an alarming difference in costs of production, and his suggested explanation was that the overhead charges of British manufacturers were too high. Overhead charges, however, did not enter into the inquiry, according to the Board of Trade instructions. Competition was not unfair, because conditions of employment in Germany were not inferior to those in this country, except to the extent of 1d. per hour in wages; but against this advantage, German manufacturers

had to meet freight and insurance charges when exporting to this country. Again, to show that competition did not seriously affect employment here, he pointed to the small number employed in the British industry.

Mr. SOPER, in his final remarks, stressed the national importance of the industry, for the reasons already given in his evidence. Gas was probably the predominant source of artificial lighting in this country; and the gas mantle was the key to modern gas lighting. It had enabled great economies to be effected in gas manufacture, because the use of the mantle had permitted valuable bye-products to be stripped from gas. He also laid emphasis upon the value of the gas mantle from the point of view of the conservation of the nation's coal resources. Mr. Soper examined the conditions laid down by the Board of Trade for the guidance of Committees, and, in claiming that these conditions had been fulfilled, added that a *prima facie* case had to be made out for a protective duty before the Board of Trade would appoint a Committee to inquire into it. The Board must have been satisfied that a *prima facie* case had been made out, or the present inquiry would not have been held. The year which he asked should be taken as a standard in arriving at a conclusion as to whether foreign gas mantles were being retained for consumption in this country in abnormal quantities was 1920, because that was the last year in which the industry was in a position to work economically and to sell at a reasonable profit. The balance-sheets of the companies concerned had shown that those companies had not paid a dividend since 1920. With regard to wages in Germany, he pointed out that when the British manufacturers had applied for a duty on German mantles under Part II. of the old Safeguarding of Industries Act, and when German witnesses came here to give evidence against the application, wages in Germany had shown an extraordinary rise. The same thing had happened in the present case. Less than three weeks ago there was again a rise in wages in one of the factories in Germany, which was due to Herr Zeigler's company having made themselves a party to an agreement to pay wages which were being paid in the chemical industry. Mr. Soper suggested that, in view of Herr Zeigler's admission that the retention of his share in the British market was a matter of vital importance to his Company, it might be a prudent action to agree to pay high wages, if, by doing so, the present application could be defeated. In his further remarks, Mr. Soper refuted the suggestion that overhead charges in this country were too high, and said his figures showed that efficiency in this country was higher than in Germany. Finally, he asked the Committee to recommend the imposition of a flat rate duty on imported mantles rather than an *ad valorem* duty, and said that he was satisfied that his suggested figure of 10s. per gross was not a penny too high; in fact, some of his colleagues considered it too low.

At the conclusion of the proceedings, the Chairman thanked the leaders and witnesses on both sides for the courteous manner in which they had put their cases and given evidence, and intimated that the Committee would consider its opinion at an early date.

The Committee's decision will be published in due course.

NORTH-EAST COAST COAL TRADE.

From our Own Correspondent.

The gloomy market conditions continue unchanged, and there is nothing new to report. The policy of working short time rather than accepting business at still lower prices is becoming more and more necessary, as buyers' ideas seem to be that every order should be taken at a little less than the one before, irrespective of what the loss to the producers may be. More and more collieries are realizing the need for making a stand, but the decreased quantities available for sale still seem to be far more than enough to meet the demand.

It does not seem likely that there can be any change in the position while the present uncertainty prevails as to the future. Both buyers and sellers are disinclined to commit themselves until it can be seen what arrangement is likely to be arrived at with regard to wages.

In gas makes, Wear Specials continue to quote 18s. 6d. to 18s. 9d. f.o.b., and best qualities 18s. to 18s. 3d. These prices are nominal, and actual business is subject to negotiation. Seconds and others are 15s. 9d. to 16s. 3d. There is practically no demand for coking sorts, and 16s. to 16s. 3d. is the price of best makes.

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

The condition of affairs in the coal trade in Yorkshire and Lancashire is gradually, but surely, assuming a very grave aspect. Many of the larger collieries are threatened with the immediate prospect of having a struggle to work even three days a week. The fate of the smaller pits with lower outputs and the increased cost of production is causing the greatest anxiety to those concerned.

House coal, which during normal times flows into the shipment areas, is held up on account of the higher rates of exchange and the keen competition from the nearer Continental producing centres; while the home market demands are, owing to climatic conditions, reduced to a minimum. The present indications of still further reduced prices even of the best industrial fuels are likely, however, to have some effect on the improvement from the larger manufacturing centres; and with coal and furnace coke reduced to present-day figures, there is some hope for the iron and steel trades.

Gas coal prices still vary, with indications that consumers are inclined more than ever to buy washed nuts and to leave screened and unscreened gas coal alone. Some collieries now stipulate that any expected offers should be in proportion for washed nuts and screened coal.

The unsettled state of the market rather inclines to the opinion that rock bottom has not been touched in respect to the figures likely to obtain for the remaining purchases of gas coal. Some of the contracts fixed months ahead of the earliest deliveries will be slightly above the average price.

There is no change in the shipping outlook, though prices have come to such a low level, showing a big loss to collieries, that it is apparent that the rates of exchange will have to operate much differently before business of any magnitude is possible.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

Drastic steps are being taken to bring the output of coal into correspondence with the shrinkage of demand. It is significant of the condition of stocks and the view taken as to the issue of the negotiations on which the working of the industry after this month so largely depends that collieries are reducing current production decisively. They can hardly do otherwise, for coal cannot be raised at anything like the prices at which some of the stocks are being liquidated. Most of the big gas undertakings have now completed contracts for the new trading year. Commitments are on a much smaller scale than twelve months ago. Apart from undelivered balances on the old contracts, industrial conditions do not dictate such a cautious policy as big consumers thought necessary when the perils of the railway strike were fresher in their memory. A number of municipally owned undertakings cannot square their accounts owing to the slump in residuals, and increased prices will have to be charged. At Birmingham the fall in the revenue from tar was nearly £70,000, in spite of increased production, and there was a drop of £21,644 on ammoniacal liquor. A reduction of 5s. has been made recently in the price of coke, representing a loss of income of £100,000 per annum. It is proposed to make increases in the scale of prices for gas varying from 3d. to 4d. per 1000 c.ft. forthwith.

CURRENT SALES OF GAS PRODUCTS.

The London Market for Tar, Tar Products, and Sulphate.

LONDON, *June* 15.

There are no particular changes to report in the London tar products market. There is a moderate amount of inquiry for pitch for next season's shipment, but buyers' ideas are below those of sellers.

There is a fair demand for creosote, but supplies are scarce for the next few months.

The demand for road tar is taking up current makes of both pitch and creosote.

Solvent naphtha is in request, and available supplies are readily absorbed. This is also the case with benzole and toluole.

Current values are as follows: Pitch, 41s. to 42s. per ton, nominal; creosote, 7d. per gallon in bulk at works; solvent naphtha, 1s. 8d. to 1s. 9d. per gallon 95/160 quality; pure benzole and pure toluole, 1s. 11d. to 2s. per gallon.

Tar Products in the Provinces.

June 15.

There is little alteration in the markets for tar products.

For pitch there has been a little more inquiry during the past week, and it is evident that some consumers would like to purchase for next season's delivery.

In creosote there has been a little inquiry, but no alteration in the price.

Benzole and solvent naphtha are in fair demand.

Crude carbolic and crystals are still neglected.

The average values for gas-works products during last week were: Gas-works coal-tar, 26s. to 31s. Pitch, East Coast, 39s. to 40s. f.o.b. West Coast—Manchester, 34s. to 35s.; Liverpool, 35s. to 36s.; Clyde, 38s. to 39s.; Benzole, 90 p.ct., North, 1s. 7½d. to 1s. 8¼d.; crude, 65 p.ct. at 110° C., 1s. to 1s. 1d., naked at makers' works; 50-90 p.ct., naked, North, 1s. 7¼d. to 1s. 8¼d. Toluole, naked, North, 1s. 6¼d. to 1s. 7¼d. nominal. Coal-tar crude naphtha, in bulk, North, 7¼d. to 8¼d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. to 1s. 2d. Creosote, in bulk, North, liquid, 5¾d. to 6d.; salty, 5¼d. to 5½d.; Scotland, 5¼d. to 5¾d. Heavy oils, in bulk, North, 6¼d. to 7d. Carbolic acid, 1s. 5d. to 1s. 6d. prompt. Naphthalene, £11 to £14; salts, £4 to £5, bags included. Anthracene, "A" quality, 2½d. per minimum 40 p.ct., purely nominal; "B" unsaleable.

CONTRACTS OPEN.

Coal.

The Bakewell Urban District Council are inviting tenders for the supply of 2500 tons of gas coal. [See advert. on p. 974.]

Tenders are invited by the Gas Committee of the Carnarvon Corporation for the supply of about 3000 tons of gas coal. [See advert. on p. 974.]

Tar.

The Edinburgh Corporation Gas Department are inviting tenders for the purchase of their coal gas and carburetted water gas tar. [See advert. on p. 974.]

An order for the repair and modernization of the purifiers at the Fleetwood Gas-Works has been placed by the Directors with Messrs. R. & J. Dempster, of Manchester. This will assist in relieving unemployment.

STOCK MARKET REPORT.

ARISING out of the failure of the recent capital issues, it is reported that further Colonial Government issues are banned for the present. The demand for fresh industrial capital is, however, increasing, and proposals involving a total issue of nearly £14,000,000 may be expected shortly. The principal of these are: Dunlop Rubber Company, Ltd., £5,000,000 5½ p.ct. Debenture at 97½ p.ct.; Union Cold Storage Company, Ltd., £3,200,000 6 p.ct. Cumulative Preference Shares of £1 at par; and Synthetic Ammonia and Nitrate, Ltd., £2,000,000 Debentures. Some of the issues are to provide for further extension of trade, which is hopeful; but the last of the three issues mentioned will not, we imagine, appeal to investors in gas companies, as it appears to be a direct challenge to the sales of sulphate of ammonia.

During the past week there were frequent bouts of heavy selling of gilt-edged stocks by underwriters with commitments on the recent issues, and prices were mostly weaker. Railways continued to be depressed; the hopes of improved traffic receipts over the holidays not being realized. Industrials were good in parts. The heavy over-subscription of the Allied Northern Newspaper Debentures attracted attention to other similar issues. Tobaccos and Silks were, as usual, prominent. Rubbers were very active; and if the price of the commodity is any indication of prosperity, there should be some good results announced later. Oils are rather a mystery. A reduction in price in gas oil last week is followed by an announcement of an increase in crude oil on the other side of the water. The fact remains that the leading shares showed improvements on the week.

Gas stocks and shares were in demand. Although most of the changes in quotations were due to interest or dividend payments, there were a number of other variations. Plymouth and Stonehouse moved up 1 point, and Hongkong and China 1½ points. The falls, however, still predominate; Liverpool 5 p.ct. ordinary, South Suburban ordinary, and Tottenham "B" with a drop of 1 point each, and Imperial Continental a drop of 2 points, were the sufferers.

The following transactions were recorded during the week: On Monday, Brighton and Hove original 167, 169, Cape Town 7¼ *ex* div., Continental Union 7 p.ct. preference 90⅜, European 7, Gas Light and Coke 83¼, 83½, 83⅝, 84, 84¼, Imperial Continental 147, 147½ *ex* div., Montevideo 67½, Primitiva 9s. 7½d., 9s. 9d., 10s., 4 p.ct. debenture (1911) 65, 66, South Metropolitan 93½, 93⅞, 94, 94¼, 94½, Tottenham 5½ p.ct. preference 104⅜. Supplementary prices, Swindon 5 p.ct., 70, 70½.

On Tuesday, Bombay 4⅞, Cape Town 7, 7⅛ *ex* div., Commercial 4 p.ct. 86, Gas Light and Coke 83¼, 83½, 84, 84⅜, 4 p.ct. preference 70⅜, Imperial Continental 146, 146⅝, 147, 149, 3½ p.ct. debenture 72½, 73, Liverpool 7 p.ct. preference 104⅝, Primitiva 9s. 9d., 10s., 4 p.ct. debenture (1911) 65¼, South Metropolitan 93¼, 93½, 93⅝, 93⅞, 6½ p.ct. debenture 103¾, 103⅞, Tottenham 5½ p.ct. preference 104, 104¼, 104½. Supplementary prices, Sunderland 6 p.ct. maximum 102¼, 102⅜, Worthing Coke consolidated 93, 93⅜.

On Wednesday, European 6⅜, 7, Gas Light and Coke 83¼, 83⅜, 84, 3½ p.ct. maximum 62, 4 p.ct. preference 79, 79¼, 3 p.ct. debenture 60⅜, Imperial Continental 146, 147 *ex* div., Primitiva 9s. 6d., 9s. 7½d., 9s. 9d., South Metropolitan 93¼, 3 p.ct. debenture 60⅜, South Suburban 5 p.ct. 95, Tottenham 4 p.ct. debenture 77.

On Thursday, Bombay 5⅛, Brentford 4 p.ct. debenture 79 *ex* div., British 7 p.ct. preference 124, 124⅛, Cape Town 4½ p.ct. 1st mortgage debenture 73½, 74, European 7⅜, Gas Light and Coke 83⅛, 83⅜, 84, 4 p.ct. preference 79, 79½, 3 p.ct. debenture 59½ *ex* div., Hastings and St. Leonards 3½ p.ct. converted 76½, Imperial Continental 146, 147, Oriental 104⅛, Primitiva 9s. 3d., 9s. 6d., South Metropolitan 93½, 93⅜, South Suburban 5 p.ct. 94⅜, Southampton 5 p.ct. maximum 81½, 82, Tottenham 4 p.ct. debenture 77, 77⅛, 78, 78⅛, Wandsworth "B" 111. Supplementary prices, Hartlepool 5 p.ct. maximum 91, St. Albans consolidated 101, 101½.

Brighton and Hove 168½, "A" 124½, Croydon 100, European 7, 7½, Gas Light and Coke 83⅛, 84, 4 p.ct. preference 79½, 79⅜, Imperial Continental 146, 147½, Primitiva 9s., South Metropolitan 93¼, 93⅜, 94, 94⅛, 6½ p.ct. debenture 103⅜, Tottenham 5½ p.ct. preference 104½, 104⅝, Wandsworth "A" 130, "B" 110½. Supplementary prices, Shanklin 5 p.ct. consolidated 100, 100½, Walton-on-Thames and Weybridge 7 p.ct. "B" 10⅜.

At the close of the week monetary conditions in Lombard Street were easier. Renewals of day-to-day advances were arranged on the lower basis of 3½ p.ct. Business in the discount market was on the small scale; and although the Treasury Bill rate was slightly higher—£4 7s. 10·41d. p.ct.—there was little effect on the open market quotations.

On the Foreign Exchange Market both francs and lire were offered freely, and the rates of these exchanges depreciated further. French francs closed at 100.22½, Belgian francs at 102.10, and Italian lire at 122.95. Sterling on New York was quiet, and the rate closed slightly lower at 4.85 27/32.

Silver closed at 31⅜d. per oz., and gold was unaltered at 84s. 11½d.

The Bank Rate is 5 p.ct., to which it was raised from 4 p.ct. on March 5. Bankers' deposit rates are 3 p.ct. The deposit rates of the discount houses are 3 p.ct. at call and 3¼ p.ct. at notice.

Premier Gas Mantles, Ltd., is the title of a Company registered recently, with a capital of £7000 in 4s. ordinary and 1s. deferred shares.

Results at Carlisle.—The annual report of the Carlisle Corporation Gas Committee states that the net profit was £2080. The number of cookers out on March 31 this year was 6309, compared with 5455 on the same date last year—an increase of 854. There has been a marked decline in the prices obtainable over the year for tar, which shows a fall of about 50 p.ct. During nine months of the year under review gas has been sold at 6d. per 1000 c.ft. less than the preceding year; the present price being 3s. 6d. per 1000 c.ft. The extension of the mains to Carleton, Dalston, Burgh-by-Sands, and Kirkandrews has now been completed. The number of additional consumers obtained thereby is very satisfactory.

Manchester Gas Accounts.—The Finance Committee of the Manchester Corporation report, in regard to the gas undertaking, that the approximate account for the past year shows that the result of the working was worse than was anticipated by £5793. The estimates provided for a deficiency of £60,801; actually the figure was £66,594. This difference is occasioned by smaller income than was estimated from the sale of tar and sulphate of ammonia, although the income from sales of gas, hire of fires, &c., and sales of coke is in excess of the estimate. The estimates for the current year provide for a deficiency of £78,929, and in addition it is proposed to meet capital expenditure out of revenue to the extent of £20,000, so that the total amount involved is £98,929. At March 31 next, the accumulated surplus of £32,172 will have been appropriated; and a deficiency of £66,757 will have to be carried forward to be liquidated out of future profits or by increasing the price of gas. The Finance Committee are in conference with the Gas Committee on the matter.

The price of gas at Blairgowrie has been reduced by 6d. per 1000 c.ft., making it 6s. 9d., less 5 p.ct.

Mr. Alan Dawson, a popular member of the clerical staff of the Exeter Gas Company, was drowned while holiday-making near Whitchurch (Salop) last week. He was 22 years of age.

The Burnley Gas Committee, having had a list of employees in the department who were over 60 years of age, have been considering a scheme for the pensioning of aged employees; but for the present further consideration is postponed.

The Lytham St. Annes Gas Department announce that, from April 1 last, the charge for gas to ordinary consumers is 4s. 4½d. per 1000 c.ft., less 4½d. discount, or 4s. per 1000 c.ft. net. Recently the Corporation gave notice of their intention to supply gas of a calorific value of not less than 525 B.Th.U. throughout the borough, in substitution for the present supply of 500 B.Th.U. in the St. Annes area and 430 B.Th.U. in the Lytham area.

NOTICES TO CORRESPONDENTS, ADVERTISERS, AND SUBSCRIBERS.

No notice can be taken of anonymous communications. Whatever is intended for insertion in the "JOURNAL" must be authenticated by the name and address of the writer—not necessarily for publication, but as a proof of good faith.

COPY FOR ADVERTISEMENTS for the "JOURNAL" should be received at the Office NOT LATER than TWELVE O'CLOCK NOON ON TUESDAY, to ensure insertion in the following day's issue.

Orders to Alter or Stop PERMANENT ADVERTISEMENTS should be received by the FIRST POST on Monday.

UNDISPLAYED ADVERTISEMENTS; Situations Wanted, Six Lines and under (about 36 words), 3s.; each additional Line, 6d. Situations Vacant, Apparatus Wanted and for Sale, Contracts, Public Notices, &c., 9d. per Line—minimum, 4s. 6d.

EDITORIAL NOTES.

Continuous Gas Sampling for Calorific Value Testing.

UNDER the Gas Regulation Act, the Gas Referees have large and highly responsible powers of prescription in respect of gas undertakings working under section 1, in order to assure the supply of gas in accordance with obligations. They can prescribe the places and times at which, and the apparatus and the method by which, tests —whether continuous or intermittent—shall be made. One limitation is that the prescribed apparatus "shall, in the case of any undertakers who have sold in the preceding years more than 100 million c.ft. of gas, and in any other case in which it appears necessary to the Gas Referees, include a calorimeter for the production of a continuous record of the calorific value of the gas which is being supplied." Thus it is seen that all undertakings making below 100 million c.ft. a year may be subjected to ordinary spot tests. This is an undoubted disadvantage to the small gas undertaking; and it was one of the main considerations in the communication which Prof. C. V. Boys, F.R.S., one of the Gas Referees, made to the meeting of the Institution of Gas Engineers. The work that he described is further evidence of the depth of interest the Gas Referees take in the operations of the gas industry within their province, and within the limits of their powers under the Gas Regulation Act. There has been evidence of this before—a desire to be practically constructive and advisory, in addition to exercising the functions relating to prescription. By the way, the prescription of a standard recording calorimeter has not yet been made. The wisdom of the delay is well recognized; but we should not be surprised to hear at any time now that the step can be taken with confidence.

It was not, however, the recording calorimeter that was the subject of the paper by Prof. Boys. It was directed entirely to the requirements of small works. In this regard, there are two matters which have impressed themselves upon the Referees. The first is that, in carrying out their duties, they have been much "oppressed" (we have not observed this, but Prof. Boys says so, and therefore it must be true) by the cost and the elaborate procedure which have grown up round the ordinary water-flow calorimeters, and which make their provision a serious burden in the case of small country places. This, it is said, applies less to the equipment within the testing-place than to the time required by the gas examiner, and the tedious nature of the operation which he has to conduct. To overcome this has not been such a serious matter as is another; and in respect of which up to the present the Referees have not found a solution which can be considered altogether satisfactory. The difficulty is this—to find a value for the average calorific value of the gas supplied when financial considerations unduly limit the number of tests. As Prof. Boys points out, if the number of tests is low, obviously there is a risk that the gas from a small works—of necessity more variable in quality than that to which most of us are accustomed—may be, on the very few occasions of test, caught at an unhappy moment when it is in a state of depression. Tests made at such times and unbalanced by tests made at more favourable times may give an unfair value for the average than has been actually delivered. This condition therefore involves the small undertaking in the constant provision of gas which is of higher value than that declared, in order that it may be safe from an adverse report. This is unjust in comparison with the large undertaking which can work (as experience testifies) very closely to the declared value. What the Referees are aiming at, to the advantage of the small works, is to attempt to introduce continuous automatic sampling of the gas for intermittent testing, so that the small works may have credit for the actual average value of the gas delivered. The idea is not a new one. It has been suggested before in connection with continuous gas sampling apparatus which has been on the market, but which is not admittedly under the similar controlling devices to which Prof. Boys subjects the design upon which he is working for the purpose of official tests of average calorific value in the small works.

How Prof. Boys has worked to reduce the triple burden —on the Gas Examiner, on expenditure, and on the small gas undertaking in regard to the security excess of calorific value—is explained in the paper. He presents and describes a complete equipment, consisting of a "Box" calorimeter, the Boys "Bell" meter, and the continuous sampling holder, with all the accessories. The constructional features do not call for reference here. Suffice it to say that simplicity and ingenuity characterize the complete equipment with the view of realizing the objective of bestowing upon the small undertaking something which will justly meet the needs, and comply with the Gas Regulation Act. Regarding the "Box" calorimeter, it is interesting to note that the water can be used over and over again. The advantages of this will be realized at once. Suitability and constancy of quality of water are requisites; and therefore the plan for re-use removes the anxiety as to doubtful quality, and ensures that the water has the same temperature as the room in which it remains and the air used for combustion. The water circulation is similar to that in the Boys recording calorimeter; and compressed cork is the insulating material. The manner in which Prof. Boys has overcome the radiation difficulty will appeal to those who have made a study of the structural features of calorimeters. From the full description given in the paper of the instrument and its operation, it does appear that the work of the gas examiner will be much curtailed and simplified, and this is what is required in a small works. As to the Boys "Bell" meter, here again a complete study has been made to provide for convenience and certainty. The meter problem in connection with calorimetry has always been a difficulty, and recurring faults have developed; but now (we hope this is well founded) Prof. Boys believes the whole of the troubles were eliminated by him in the meter he designed for the recording calorimeter. Most of the features (there is only one exception) have been incorporated in the "Bell" meter as adopted for independent use. The ease with which the water level can be ascertained and maintained is attractive. In short, even if there were no other grounds of indebtedness, Prof. Boys would have to be heartily congratulated upon the work he has done in this respect alone. From the knowledge of the meter and its working, he claims for it accuracy, convenience, and permanence over the usual form of meter. There is one

precaution which has to be taken. Where the meter is left in a room which falls in temperature, the glass cools more than the water; and this has the effect of completely obscuring the view, and makes observation impossible. Where this occurs, a protecting case should be used.

With regard to the testing of a continuously drawn sample of gas to obtain the average value between one testing and another, this is only at present put forward as a possibility which the Gas Referees could adopt, if found satisfactory, but not otherwise. It will be a considerable advantage if this can be done; and then we should feel that, in the complete equipment, the small works would have a reliable method of having justice done to its gas, and one which would relieve the examiner, and enable him to get through more work—especially when, as is the case in some of the smaller works, the same examiner is engaged by a group of local authorities. A complete test can be made with the "Box" calorimeter in 25 minutes; the gas being burned at the rate of 1 c.ft. per hour. This indicates that in connection with the continuous sampling of the gas, a very small holder will suffice. Another important thing is that for the small works a minimum of cost will be involved by this interesting and ingenious equipment. At the Institution meeting, the appreciation by the gas profession of the work of Prof. Boys found expression in a manner which must have assured him of its perfect genuineness.

Complete Defeat of the Chemical Manufacturers.

The gas industry appears to have to be perpetually on the defensive in respect of their rights, and this not only in regard to the preferential treatment by the Government of their chief competitor—electricity—but in connection with their secondary products. It should be the duty of the Government to see that a statutory industry serving the public, under adequate safeguards for the latter, should be allowed, by the utilization of its own resources, to function with the view of rendering public service with the utmost efficiency and economy. There has latterly been frequent discussion of the position in regard to electricity. To-day consideration must be given—and this can be done with great satisfaction—to the attitude of the chemical manufacturers to our industry. For years the chemical manufacturers have fought with the view of circumscribing the gas industry in its dealings with secondary products. Up to a point they succeeded, by securing (not through the general inquiry that was held) the one-third purchase restriction. That curtailment of power, although at present it has had no real mischievous effect, has always been highly objectionable, because it is a barrier to one of the industry's outlets for possible development in the quest for economies in the interests of the primary commodity and public service. Whatever can be done in the present or the future—perhaps by combined working—ought to be permitted if it is to public advantage. The chemical manufacturers have been making a fresh essay to curb gas undertakings by attacking the Gas Light and Coke Company with a persistency through the Law Courts which, in itself, was sufficient evidence that they meant to succeed in this new effort if argument and money expended on legal costs could win. *Deuchar v. The Gas Light and Coke Company* is how the case will in future be known; but no secret has been made of the fact that Mr. Deuchar was merely representative of a group of chemical manufacturers. When they started on this adventure, it was a big speculation; but they would not have pursued it from the first Court through the Court of Appeal to the House of Lords, had they not had visions of success. But every Court has been against them; the decisions have been unanimous from first to last. Not only so, but the Lord Chancellor (Viscount Cave) and Lords Dunedin, Atkinson, Sumner, and Buckmaster were also unanimous, and were so on the arguments alone of Counsel for the appellant. It is rarely that there is such complete unanimity. Naturally, the chemical manufacturers will not be satisfied with the result; but they must admit that their defeat was complete, and that their interpretation of the powers of the Gas Light and Coke Company was wholly unwarranted and wrong. It has been a costly matter for the chemical manufacturers to prove their error, and that the Company were not acting in contravention of their statutory authorization. We congratulate the Company, and at the same time recognize that the result has not only individual importance, but is of great value to the whole gas industry.

The argument before the Lords of Appeal and the judgments were reported in our last issue [p. 967]. The chemical manufacturers through Mr. Deuchar sought an injunction to restrain the Company from manufacturing caustic soda which they require in the conversion of naphthalene into beta-naphthol. It can readily be seen that, if the application for an injunction had succeeded, the Company would have been compelled to purchase their caustic soda from the chemical manufacturers, and the decision would have been available for application in many other directions—not only by the chemical manufacturers, but by other branches of trading. For example, what would have prevented an electricity supply undertaking applying for an injunction to restrain a gas undertaking from producing its own electrical energy for operating its machinery? If there is efficiency and economy (and so public advantage) in a gas undertaking producing any chemical or anything else for the purpose of its own business as compared with purchase from an outside source, why in the name of common sense should there be restraint? It is easy to see that a big principle was at stake in this case, and one which would have had far-reaching detrimental effects had it gone against the Company. Their Lordships, as the arguments show, fully recognized this. It was all a question of the interpretation of the powers under which the Company operate; and their Lordships agreed that Parliament, in giving the powers to work up secondary products, intended that they should do so in the most efficient and economical manner possible. To hold otherwise would be a distinct obstruction to progress and development. In this connection, the Lord Chancellor quoted, from the case of the *Attorney-General v. The Great Eastern Railway Company*, the view of Lord Selborne: "I agree with Lord "Justice James that the doctrine of *ultra vires* ought to be "reasonably, and not unreasonably, understood and ap-"plied, and that whatever may fairly be regarded as inci-"dental to, or consequential upon, those things which the "Legislature has authorized ought not (unless expressly "prohibited) to be held, by judicial construction, to be *ultra "vires*." Their Lordships agreed that the manufacture of caustic soda was incidental to the conversion of naphthalene into beta-naphthol. As to the manufacture of caustic soda by the electrolytic process producing chlorine, and that with caustic soda and chlorine one can make an enormous number of saleable combinations, the Lord Chancellor said the chlorine was a necessary bye-product in the process of making caustic soda, and he regarded it as a small matter. After this complete defeat, perhaps the chemical manufacturers will devote themselves to their own immediate businesses which they are allowed to develop in those ways which will produce the highest efficiency and economy, and leave the gas industry to do the same. The fact that gas undertakings are statutory concerns, while chemical manufacturers are free, should not place upon the former restraints which would be disadvantageous to them and directly advantageous to the latter.

Centenary of Benzene Discovery.

The benefit which the discovery of benzene by Michael Faraday conferred upon the world defies measurement. Words to that effect were used by Lord Balfour at the wonderful centenary celebrations of the discovery held in London last week, when the primates of the scientific world assembled to do honour to one who was a prince in science. The words are true. The discovery has had world-wide effects—in the building of industries, in creating employment, in beautifying life, in increasing the scope of art, in assisting in providing for transport on land and in the air, and in another direction of which much was heard during the terrible four-and-a-half years which succeeded Aug. 4, 1914. Faraday little knew the place his discovery would take in the world's affairs and activities in peace times and in the disturbed periods of war. As Dr. H. E. Armstrong so aptly put it last week, the discovery has proved one of the most fundamental of chemistry. It was only fitting that the gas industry should have had representatives taking part in the celebrations; for it has done much, and is doing it daily, in releasing from coal the elements from which benzene is derived. The work in this

connection of the carbonization industries and of the Benzol Association was referred to by Dr. Armstrong; and among those who heard there are few who know of the magnitude of that work better than Mr. D. Milne Watson, Mr. E. V. Evans, Sir Dugald Clerk, and several of the scientific men—such as Professors Bone, Frankland, and Perkin—whose names are linked in one way or another with the gas industry.

The speeches that were made at the celebrations by the Duke of Northumberland, Lord Balfour, and many distinguished scientists, constitute a perfect gold mine in lessons for the individual and the nation. A new discovery may appear at first blush to be a small thing. Its real value to the world can only be tested and proved by time. A discovery is a germ; it may be one that will have prolific growth, but not till the growth is an accomplished fact can we estimate its true worth. A hundred years away from this discovery, we can look back upon the developed inestimable utilities of benzene; Faraday himself, intellectually brilliant and far-seeing as he was, could not penetrate the hundred years that were to succeed the discovery. He could not have precognition of the further discovery by William Henry Perkin of the aniline colours, the first of which was mauve. Nor could he foresee that his discovery succeeded by that of Perkin would so vastly enrich—not this country, but Germany, through the profound inappreciation by the Government in power when this great contribution was made to the riches of the world. So, however, it was; but that particular lesson from the history of benzene should cause the Government of to-day to give good heed to the products of science in the interests of the nation. Discoveries which indicate the possibility of new industry or the development of existing industry are more worthy of Government encouragement than many other things upon which they set their minds, put their hands, and spend money from the Exchequer. Lost industries are difficult to restore; in this regard no lesson of greater acuteness presents itself than the dye industry, and all it has involved in attempting to establish it on a firm basis in this country. British discovery through research or inventive genius must not again be permitted to pass hence for the foundation of industry in a foreign country to the detriment of this one.

The Duke of Northumberland, at the celebrations, said one of the most distressing features of the times is the failure to link-up scientific discovery and methods with public service. Thankfully we discern a change in this condition, through the Department of Scientific and Industrial Research, the National Physical Laboratory, and the Board of Fuel Research, with Government grants to research in other directions. We are as a nation safeguarding ourselves. But even now it cannot be said that all is being done that should be done. There are complaints that, while there is recognition of a great need for research and of applying its fruits, there is all too little regard for its sufficient support; and big results and parsimony have never gone well together. Before us is spread another lesson in the depressed state of industries and the mass of unemployment, the dimensions of which sometimes give signs of diminishing, and then a reaction sets in, until now unemployment is again working towards a fresh peak in the curve. To help to diminish the severity of movements in industrial activity and in the volume of employment, the foundations and structure of industry require to be developed by greater application to our scientific and research resources. It is a matter of good Government to look well and generously to these factors; and the degree of future national prosperity rests very much upon the measure of which is done in this direction. There are, however, things that appear to be lacking in our scientific and research work to-day; and they are system, co-ordination, and definite objectives. In our research work for the solution of problems and the making of discovery for which the nation pays, we seem to jump from one thing to another with surprising alacrity, and hear comparatively little of the objectives and their realization. There is much work that should be done, and must be done initially, to set in order scientific research with the view of bringing to the country the maximum material results. These may not be immediately attainable; but scientific research carried out for the nation, and financed by it, should be placed in a position impregnable to genuinely adverse criticism.

To return to the celebrations of the centenary of the discovery of benzene, much was said as to the life of Faraday. It was a life devoted to science—science directed to practical ends which have been incalculably beneficial to mankind. Faraday was a modest and devout worker; but the brilliance of his accomplishments made him one of the great luminaries of the scientific world. He could not, however much he tried, divest himself of outstanding distinction and greatness. His life and work are before us for emulation by those who, with scientific attainments and ability, have yet their lives before them. We are grateful for the fact that the gas industry has an important link with Faraday, and we are pleased that the industry has been one of the vehicles through which the benefits of his discovery of benzene has developed so much value in the world. It is interesting to know that a medal is being prepared which is to be awarded without regard to nationality, for outstanding achievements having clear relation with the discovery of benzene. The first recipient of the medal is Mr. James Morton, in special recognition of the signal services he has rendered to science and industry in this country, during the last ten years, by developing and extending the manufacture of anthracene dyestuffs, and more recently by extending their application to silk and wool. The discovery a hundred years ago, and the developments that have been made upon it, have for the country powerful lessons which, if observed, should be bountiful in their results.

The Misfortunes of Coal.

ADVERSITY still obstructs the coal industry; and at present there does not appear even a loophole for escape. The relatively poor exports of coal, particularly to Germany, France, Belgium, and the Netherlands, continue. The position to which things have descended in this regard is well attested by the experiences of the first five months of the year. During that period, over 11 million tons of coal less were sent abroad than in the corresponding period of 1923, and more than 4 millions less than in that of 1924. The actual figures were: 1925, 22,114,598 tons; 1924, 26,248,766 tons; 1923, 33,220,230 tons. In addition to the falling-off in quantity, the values to-day are comparatively low. In the last five months, the total value of the exports, according to the returns, was only £23,143,815. In the same period last year, the value was £32,274,947, and in that of 1923, it was £41,464,651—an enormous drop in revenue for five months. In view of this, and the continued depression in our industries at home, it is not at all surprising that more collieries have been closed, and therefore there is more unemployment in the coal industry, as well as in coal-shipping, and in other sections of its transport.

In face of this, firebrands like Mr. A. J. Cook still talk of what he and others like him will do if they can get the major Trade Unions to follow their communistic flag and directions in the quixotic attempt to get more money for the miners, without in return giving more output to reduce the cost of production, so that a stronger competitive position can be built-up. The economic limits have been passed in many collieries; and the talk of visionaries and extremists will not change them. So much so is this the case (and we are extremely sorry to see it) that the excellent co-operative experiment at the Vauxhall Colliery, near Ruabon, came to an end—much to the regret of the participants—last Wednesday. Solely due to the diminishing price of coal is the fact that the colliery cannot be carried on at the present piece wage rates, which have to be coupled with the severe competition from the coal of other countries. The Resident Engineer at the colliery says that, if the sale price obtained in March had remained unaltered, the colliery would have been working to-day at a profit, and that through the increased exertions of the men. All concerned have been completely satisfied with the results of the experiment; but outside causes prevent its continuance without a revision of the terms. The output per man increased, and consequently the working costs were considerably lowered. It only required maintenance of the prices ruling about three months since to enable this really co-operative effort still to be a success. The colliery owners have made a suggestion to the men. Whether or not they will be able to accept it remains to be seen; but anyway the Company, it is stated, are willing to consider any scheme which the men may themselves put before them, subject to the project being one which would not occasion any loss.

Regarding the inquiry into the economic conditions of the

industry, there were two days' sittings last week of the Joint Committee of the Mining Association and the Miners' Federation. Up to the time of writing, there has been no official announcement as to the results arrived at. There is no mistaking the causes of the condition of the industry; they are as plain as the Houses of Parliament. But now that they have been discussed, the question of what is to be done is a more delicate matter. It was expected by the miners that the inquiry would have assumed a definite form last Thursday; but no positive suggestions were put forward from either side. It was, however, arranged that a further sitting should be held yesterday, when it was hoped that the owners would submit proposals for consideration. The idea is that the Mining Association will suggest something in the nature of longer hours or lower wages. That appears to us a very intelligent prognostication, in view of the fact that it is difficult to see what else they could propose. But, of course, working hours could not be altered without legislation, and by agreement with the miners. The prophets say that, if longer hours or reduced wages is a correct forecast of what the Mining Association will propose, then the miners will launch their new wage programme, and make counter demands, including a wage based on the cost of living. We must "wait and see" what is actually the upshot of the inquiry and discussions. But at the moment, though the indications are clear as to only a single course being open to both sides, one side at all events will (if previous threats are reliable) object to pursue it. If this be so, then the certain thing in store is that matters will go from bad to worse, because no union of labour, however strong, can override economic reverses. What they can do is to work, if they choose, to mitigate them.

Coke Competition.

The Editor of the "Journal" thanks the competitors in the Coke Competition whose papers have already been received. May we remind those who have still to forward their contributions that the latest date for their reception is next Tuesday, June 30?

Speculation and Ignorance.

At the Faraday celebrations last week, Dr. H. E. Armstrong made use of these words: "We are too prone to speculate—often too inconsiderate in speculation—but little alive to our own individual ignorance, too little apt to cultivate that breadth of vision and proportionate judgment which are at the root of scientific method." As we read these words, our mind travels over the advocacy of low-temperature carbonization for the making of gas for the supply of the needs of cities and towns.

Nota Bene.

It is observed that, through the influence of gas engineers and managers in different parts of the country, extracts have appeared in local papers from the Presidential Address of Mr. J. Ferguson Bell to the Institution of Gas Engineers. This is an excellent idea, and advantage should be taken of all possible occasions to obtain similar publicity in all quarters of the country. In one paper before us, the points of the address particularly noticed are the progress of the gas industry in public service, and the discussion as to the intentions of the Government regarding electricity supply.

Gas from Fuel Oils.

A good deal of attention appears to have been directed recently to the production of gas from heavy fuel oils; and it is suggested that this will compete for industrial purposes with town gas. It is more likely that, if fuel oil gas comes along in practicable and commercial form, it will compete not with town gas, but with producer gas. We have lately been hearing of the "Hackol" process (introduced by Mr. J. E. Hackford), in which heavy oils of a specific gravity of ·950 and upwards are used. Much experimenting has been necessary in order to discover a generator which is free from objection. Mr. Hackford believes he has found one, which relies upon the heat of partial combustion to provide a sufficient temperature to crack the oil into gas, and to carry on the cracking indefinitely. It is also claimed that a constant composition of gas is maintained; and that its thermal value is from 155 to 190 B.Th.U. per c.ft. Only a small space is required for the generator. The inventor suggests the possibility of selling the gas at about one-third the price of town gas, and at about 66 p.ct. of the price of producer gas with coal at 24s. per ton. Are these prices based on the respective thermal values? There will be no disturbance in the gas industry over this competitor any more than there has been over the introduction of producer gas. Should a greater demand in consequence grow for fuel oil of the class mentioned, present prices will ascend. It is not only space that counts with manufacturers in preferring to pay more per therm for gas on tap, but the trouble and inconvenience of running and maintaining a plant and storing the gas-producing materials. However, it will be interesting to have the results of working experience with the generator before definitely criticizing it and its performance. There is also reported from the United States an improved method of oil carburetting, which permits oils formerly regarded as fuel oils to be used for gas making. In this system no chequer work is used, but the cracking is effected by the hot refractory lining of the vessel and also the crown of the chamber.

Repetition.

We have had a fresh delivery of the prospectus of the South Midlands and Berkshire Electric Light and Power Company, Ltd. The "Limited" should be emphasized. The Warwickshire and South Midlands Electricity Supply Corporation, Ltd., are still offering, in the South Midlands and Berkshire Company, 9500 8½ p.ct. cumulative participating preference shares of £1 each, the income-tax on which is free up to 4s. 6d. in the pound; also 1000 7 p.ct. (guaranteed) first mortgage debentures at £98 p.ct. in multiples of £10 each. This is the undertaking which proposes to acquire a controlling share, debenture, and administrative interest in the Eynsham Gas Company, Ltd. It is intended "to instal electric light in conjunction therewith;" leaving gas to look after the heating, cooking, and power for the district. We are glad to see that these 43, Cannon Street, people are mindful of the advantages of using coke for steam-raising for the generation of electricity. But the title of the Company, the capital, the report of the Auditors, Turner & Co., and much else are an insult to people of ordinary intelligence. We hope there are not many below normal intelligence who will be persuaded to invest in the concern. The mention of the Warwickshire and South Midlands Company reminds us of the Barford inquiry, in which Turner particularly cut such a melancholy figure; and he and the prime mover, Eaton, thought fit not to be present at the second day's proceedings [see *ante* p. 445].

FORTHCOMING ENGAGEMENTS.

[*Secretaries of Gas and Kindred Organizations are asked to assist in making this diary of events as complete and useful as possible by sending the earliest intimation of all meetings.*]

June 26.—Waverley Association of Gas Managers.—Annual meeting at No. 129, Princes Street, Edinburgh. There will be an address by the President (Mr. R. Taylor, of Aberlady), and a paper on "Gas Ovens," by Mr. Arthur Forshaw, M.Sc., Chief Chemist to Messrs. R. & A. Main, Ltd. Luncheon and an afternoon drive and steamer cruise are included in the programme.

June 30.—Last Day for Coke Competition Papers.

July 9.—Coke Oven Managers' Association (Midland Section).—Visit to the works of Messrs. Stainby and Lyon, of Knottingley.

July 20-25.—Royal Sanitary Institute.—Congress at Edinburgh. H.R.H. the Duke of York has accepted the Hon. Presidentship of this Congress, at which Sir John Gilmour, Bart., Secretary for Scotland, will preside, and deliver the Inaugural Address. A health exhibition is to be held in connection with the Congress.

Sept. 15-17.—Irish Association of Gas Managers.—Annual Meeting in Belfast.

Oct. 19-21.—British Commercial Gas Association.—Annual Conference and General Meeting in Plymouth.

PERSONAL.

Mr. J. NEWELL REESON, Engineer-in-Chief and Technical Adviser to the Metropolitan Gas Company of Melbourne, is visiting England. Letters may be addressed to him, c/o Messrs. John Terry & Co., No. 7, Great Winchester Street, E.C. 2 (Agents to the Company), or c/o Union Bank of Australia, Ltd., No. 71, Cornhill, E.C. 3.

Mr. T. ANTHONY CANNING, Technical Assistant Engineer to the Newport (Mon.) Gas Company, and Past-President of the Wales and Monmouthshire Junior Gas Association, has been elected a Fellow of the Chemical Society. He is the eldest son of Mr. J. Herbert Canning, O.B.E., F.C.S., the Engineer and Manager to the Company.

Last month the Bombay Gas Company appointed Mr. CHARLES DONOVAN TERRY as their Assistant Manager and Engineer. Mr. Terry went to Mr. R. S. Ramsden as a pupil in 1920, and since completing his indentures had been on the technical staff at the Leamington Gas-Works. Before leaving for Bombay, he was presented by the staff and workpeople at Leamington with an inscribed wrist watch. Mr. Terry is the son of Mr. C. E. Ryder Terry, who has been connected with the gas industry for very many years.

Mr. JOSEPH WATSON, of Purston, has resigned from his position as Secretary to the Ackworth, Featherstone, Purston, and Sharlston Gas Company, after having held the position for about 49 years. He will be succeeded by Mr. THOMAS WALLER, who has retired from the Directorate of the Company to take up the duties.

Congratulations to Prof. J. W. COBB, C.B.E., B.Sc., F.I.C. He has been appointed Pro-Vice-Chancellor of the Leeds University. Although this election is a distinction which, we are sure, Prof. Cobb prizes very highly—particularly as coming in the first instance from his colleagues of the Senate—it is not a permanent office, and does not in any way supersede his appointment as Livesey Professor and Head of the Department of Coal Gas and Fuel Industries. The office was held, for instance, by Prof. Smithells at the time he resigned his Professorship of Chemistry, which he held along with the Pro-Vice-Chancellorship. One feature of the appointment, of which Prof. Cobb naturally must be proud, as indicating the position which Applied Chemistry has won for itself in the University of Leeds, is that for the first time the Senate have nominated as Pro-Vice-Chancellor a member of the Faculty of Technology.

The retirement on the 12th prox. of Mr. J. OLLIS, Chief Officer of the Public Control Department of the London County Council (of which mention was made at the recent annual meeting of the Association of Statutory Inspectors of Gas Meters), is referred to by the General Purposes Committee, who point out that he entered the service of the late Metropolitan Board of Works in 1882, so that he will have served the Council and their predecessors for a period of over 43 years, including nearly 19 years as head of the Public Control Department. The Committee desire to place on record their appreciation of the long and valuable services which Mr. Ollis has rendered to the Council and to London. His work has, they point out, embraced a wide variety of subjects, necessitating the display of considerable organizing ability and tact.

ELECTRICITY SUPPLY MEMORANDA.

THE protest of the gas industry against the suggested subsidizing of the electricity industry by the Government has raised greater interest in the subject than has done any other publicity; and it has even stirred some of the men in the electricity industry, who had only indolently looked at the subject from a distance, to make a close examination of it. We are charmed to remark that the electrical journals have thought fit to take notice of what is being said on the subject by the gas industry; but as is their strange custom, instead of treating the matter seriously, certain of them refer to what is said with a thin jocularity, and without any real attempt at controverting the points. This is all to the good. It evidences well the soundness and sense that reside in the arguments advanced by Mr. D. Milne Watson and others. There is another observation which shows how curiously erratic the electrical writers can be. Some of the very men who deride when the gas industry speaks on the subject have previously written against Government interference, have spoken of the risks of too much concentration of electricity generation, have mentioned that the increased transmission costs will negative slender savings in coal for generation, and have questioned whether any Government can, through electrical legislation, create a new heaven upon this much troubled earth by restoring industry, by way of electric power, to a state of prosperity—albeit the high costs of materials, labour, machinery, rates and taxes, and a few other odds and ends which go to make up industrial costs combine to inflict a load which has defeated all the best efforts of our brainy industrialists to gain ascendancy over their difficulties. Yet, when gas men who administer large interests, and have incomparably more business experience than their critics, speak against the principle of Government subsidies for industry, and point the mistakes of the politicians as to what electrical power can do or cannot do in re-establishing industry, the electrical writers are content to ridicule instead of to deal with the matter with a sense of responsibility. As we say, this is excellent, because anyone with an ordinary amount of intelligence will know why they do it. Anyway it would be an advantage if they would not, in their desire to ridicule the gas men who speak on the subject, change their own attitude in relation to it. A see-saw policy does not manifest a good balance.

A Good Sign.

Since the addresses and speeches of Mr. Milne Watson criticizing the electrical intentions of the Government, there have been several letters in the daily Press. We have referred in previous "Memoranda" to some of the more interesting of these. There has been interest in reading another published in "The Times," by Mr. R. W. Dron, of Glasgow, in which he alludes to the expectations that have been raised by one political party after another regarding schemes of electrical development and coal carbonization. Those "expectations," we remember, have ranged from a saving of sufficient coal and money to pay off the National Debt in a few years to the placing at the disposal of every rural cottage electrical energy at a price never before dreamed of for lighting, heating, cooking, knife and boot cleaning, and for making land crops grow in a manner which they have never shown any disposition to do before, and to place the cow under the operation of yielding her product in a style which will give happiness and delight to both her and her owner. These predicted miracles have made many electrical men blush, and they have remonstrated with the authors because they know full well that their dream cannot materialize; for any attempt to cause it to do so would simply add costs which would make the supply generally dearer than cheaper. Through these vague and idiotic promises, Mr. Dron finds that the public, although somewhat confused by them, are inclined to acquiesce in the expenditure of vast sums of money in the hope that the results will follow in due course. If this expenditure takes place, there will in good time be enlightenment as to what will really happen. On this point (as on others) Mr. Dron makes a sensible remark. He says it should be clearly realized that the burden of the expenditure in super-power stations, main transmission lines, and the standardization of frequency will fall on our industries to-day, whereas the benefits, if there should be any, will only be reaped in a somewhat remote future. We talk of Government subsidies; but nothing much has been said of the sources of such subsidies. The greatest taxpayers are industry and commerce; so that what the Government are proposing to do—we emphasize the word "proposing"—is to make the cost of electrical energy a shade lighter, and to extract largely from industry and trade the money to do it. We see no advantage in that; and should the attempt fail, it will be another illustration of the stupidity of political interference in a matter which is best left to development in the natural course of things, and by those competent and interested in bringing about the best conditions. Again and again, says Mr. Dron, it has been demonstrated that the proposed super-power stations cannot effect the reduction in overhead costs which optimistic politicians predict, and that the provision of main transmission lines in advance of the probable demand for electric supply is an uneconomic proposition. While the standardization of frequency is for many reasons desirable, at the present stage of development the technical and financial difficulties are enormous, and the resulting benefits are very problematical (though Mr. Dron does think this is a different matter) that it would be a good thing if a standard frequency —say, 50 cycles per second—were adopted for future developments. We agree fully with him that "before the country sanctions capital expenditure, on the schemes of politicians, it must be demonstrated that the call for these is urgent, that the results are reasonably assured, and that there are insuperable difficulties in the way of private enterprise. Certainly these conditions have not been complied with in the political proposals for electricity or coal carbonization."

Commonsense Considerations.

The electricity reorganization schemes of the Electricity Commissioners appear to advance to a certain point, and then come to a dead-stop. Precisely as we thought would be the case—what the Electricity Commissioners would like to see come about by quick process is being largely accomplished by allowing things to take their own

Developing Without Joint Machinery.

developing course. Take, for example, the Aire and Calder Electricity District. The local authorities in the West Riding have received from the Directors of the Yorkshire Electric Power Company a communication in which they state that they have reluctantly decided that further attempts to carry out the Commissioners' scheme for the reorganization of supply in the Aire and Calder District will be of no avail. Therefore, the Company are proceeding with the development of supply as entrusted to them in their last Act. In respect of uniformity and efficiency of supply, the position in the West Riding has already reached the development sought by the Commissioners. Working in close co-operation, the Power Company and the large municipalities are at present producing about 90 p.ct. of the electricity sold in the area, and elimination of small and uneconomical stations is proceeding in a natural manner without recourse to any joint scheme such as was formulated in 1921. The complete supersession of the few remaining small generating stations is assured by the provision which is being made for extensions. Then why trouble about a Joint Authority and compulsory powers?

Cheaper than Gas.

Our electrical friends suffer from a peculiar twist in their imaginations, and hyperbole with them is sound reasoning. On May 27, we referred to the heating of bath water at Poplar by means of electricity; in the "JOURNAL" for June 3, there was published a letter from Mr. Horace Bowden; and a comment on it appeared in the "Memoranda" on June 10. Our electrical friends regard, as a proper basis for comparison in this matter, electricity supplied at a shade above the average cost of coal delivered at the electricity station, as against the ordinary flat rate cost of gas in the district. We are sorry to see that they persist in looking upon this as perfectly fair, while at the same time failing to recognize that they are paying a tremendous compliment to gas. "Meteor" in the "Electrical Times" says that, in his original allusion to the matter (to which reference was made in our comments for May 27), he showed that electricity actually worked out cheaper than gas for heating at the Poplar Public Baths; and the advantage was so considerable that the use of gas was discontinued. The contributor of "Cooking and Heating Notes" to the same paper remarks that the gas industry does not like it noised abroad that electricity has proved cheaper than gas for water heating at the public baths, and that the gas apparatus has been removed in consequence. Whether or not Mr. Bowden can justify the supply of electricity at a price a shade above the average cost of coal delivered at the generating station is not at the moment the point in dispute, though we deny absolutely that that gentleman has in any way justified the charge from the commercial point of view. What we are complaining of is that there has been no justification of a comparison of that charge with the figure at which gas is supplied for lighting in the district. Apart from this, in our original criticisms, there were various matters referred to, to which neither Mr. Bowden, Mr. Hope, nor our friends of the "Electrical Times" have replied—one of them being the amount of coal that, on Mr. Bowden's own data, must be used at the electricity generating station in excess of coal-fired boilers to obtain the same quantity of heat for raising the temperature of the water to the point mentioned by Mr. Hope in his paper. In the "Electrical Review" we notice a letter from Mr. J. E. Gilbert, in which he says that, to the superficial reader of Mr. Hope's paper, his conclusion may be misleading, inasmuch as he has compared a moderate electric storage system with a very out-of-date coal-heated type. Mr. Gilbert contends that, had the Baths Superintendent at Poplar experimented with his 4000-gallon tank with heat derived from small coal or anthracite furnaces, the results would have been more satisfactory. However, all that our friends seem to be able to do is to thump on the note that electricity at the Poplar Baths, supplied at a cost a small fraction above the average cost of coal delivered at the generating station, is cheaper for heating water than gas supplied at the local lighting rates! We think, as they cannot do better than this, we may leave the matter, with a further remonstrance to "Meteor" as to a statement which appeared in his notes for June 4, that the "JOURNAL" wrote that "selling electricity at the cheap rate in question is said to be an impudent stunt." As a matter of fact, the words "impudent stunt" were taken from "Meteor's" own notes preceding our first reference to the matter. He then remarked "Our friends the gasmen always assume the electric heating of water to be an impudent stunt." We are sorry that in "Meteor's" excitement over the matter, his own expressions and phrases are attributed by him to us. Perhaps in calmer moments he will recognize that this is not cricket, and will remember that there have been other occasions on which it has been necessary to make the same protest, in view of his propensity for extravagance.

Mr. Walter S. Allen, J.P., who was Chairman of the Atherstone Gas Light and Coke Company, Ltd., left estate of the gross value of £24,027, with net personalty £22,375

OPENING OF NEW SHOWROOMS AT LOUGHBOROUGH.

On Thursday, June 11, new showrooms and offices of the Loughborough Corporation Gas Department were formally opened by the Mayoress, Mrs. G. H. Bower.

Situated in The Rushes, the new building has on the lower floor a polished teak shop front with two large plate-glass windows on either side of the entrance doorway, with leaded lights above. The upper floor is in brickwork, with Tucker's "Multiruf" facings. In the centre is a large oriel window with gabled roof, which is covered with Westmorland slates. On entering the building, one is at once in a convenient showroom, 34 ft. long by 19 ft. wide, with a polished hardwood floor, and fitted with special arrangements for displaying in operation the latest gas fires, geysers, cooking ranges, and lighting burners. Among the latter are indirect bowl fittings with distant control. At the back of the showroom is an oak counter and screen dividing-off the cashier's office; and at the rear of this is the Manager's office, the general clerks' office, and book room. On the first floor, reached by a staircase at the side of the cashier's office, are the Committee room and a store room. The building was designed by Messrs. G. H. & A. M. Barrowcliff, Architects, of Loughborough, and erected, under their supervision, by Mr. A. Faulks. On the new building coming into occupation, the Manager's office in Green Close Lane will be used as a gas testing laboratory.

OPENING CEREMONY.

The Mayoress was presented with a silver-gilt key, suitably inscribed, by Mr. A. M. Barrowcliff, the Architect, with which she unlocked the building.

The MAYORESS, in declaring the offices open, said she had noticed with satisfaction the improvements in cooking stoves, which, she hoped, would benefit the users.

Mr. G. W. LLOYD JAMES (the Chairman of the Gas Committee) moved an informal vote of thanks to the Mayoress.

The visitors and guests then made a tour of inspection of the showroom. Afterwards about a hundred of the company adjourned to the College canteen for tea, at the invitation of the Chairman and members of the Gas Committee.

Col. PIERCEY, in proposing the toast of the "Loughborough Corporation Gas Department," congratulated Mr. James and his Committee on the handsome offices they had built, and complimented the Manager of the gas-works, Mr. E. Onions, upon the ability he had displayed.

The CHAIRMAN, in reply, referred to the early history of the gas-works. They were originally established by Mr. G. Livesey, and were purchased from him in 1836 by a Company for the sum of £1686, the plant at that date being necessarily small. In 1868 the Local Board decided to seek Parliamentary powers to purchase the undertaking, but at a meeting of ratepayers an adverse vote was recorded, and the proposal was dropped. Thirty-one years later, in 1899, the authorized capital of £48,750 having been expended, the Company were seeking powers to increase their capital, when the Corporation also decided to promote a Bill for the purpose of acquiring the undertaking. The Corporation were successful, and the Company withdrew their Bill. The purchase price was determined the following year by arbitration, and the Corporation entered into possession on July 1, 1900. The cost of the undertaking to the Corporation was £102,154—more than double the capital value of the Company. The amount of gas made in 1900 was 70 million c.ft. To-day it was 160 millions. The number of consumers in 1900 was 2500, while at present there were 6156. Gas for cooking was not so popular in 1900, the number of stoves at that time being 400. To-day there were 4794 stoves in use.

PRESENTATIONS.

A presentation by the employees of the Gas Committee was made to Mr. Onions. This took the form of a smoker's cabinet, which was handed to the Manager by Mr. Sutton, who has been in the gas-works 53 years. A presentation of an inscribed piece of silver plate was made to Mr. Onions by the Gas Committee.

Institution of Civil Engineers.

At the Conversazione of the Institution of Civil Engineers, which was held on Wednesday last, there were one or two exhibits of interest to readers of the "JOURNAL." Dr. J. S. Owens exhibited his method of counting dust particles with the settlement dust counter, and showed microphotographs of the dust particles in the air taken outside Vigo Harbour, at the mouth of the St. Lawrence River, and in Surrey. Slides demonstrated the flue dust from a hand-fired boiler furnace and from a pulverized coal fired furnace. A cement-spraying apparatus was shown by Prof. S. M. Dixon. This machine throws cement mortar by a jet of compressed air. The mixture is blown through a rubber tube 2½ in. in diameter, without nozzle. The mixture ordinarily used is 6 to 1, fairly dry; and the coating becomes hard immediately. The air required is 220 c.ft. per minute at a pressure of 3·5 atmospheres; and the amount of cement thrown is 1 cub. yd. per hour. Carbon dioxide measuring instruments, due to Dr. Ezer Griffiths, were exhibited by the National Physical Laboratory.

CENTENARY OF BENZENE.

Honour to Faraday.

THE centenary of the discovery of benzene by Michael Faraday was celebrated on Tuesday, June 16, by the Royal Society, the Chemical Society, the Society of Chemical Industry, and the Association of British Chemical Manufacturers. The lecture theatre of the Royal Institution, in which the gathering took place, was filled by many distinguished scientists of this country and from many parts of the world.

The Duke of Northumberland (the President of the Institution) received delegates from many institutions, and said they were met to honour the discoverer of benzene and to call the attention of the rising generation to the motives which inspired Faraday's life, which made him a great scientific genius and a great man. The discovery of benzene had had the greatest material effect on the world, as being the foundation of the major section of organic chemistry. It was directly or indirectly the raw material from which manufactured dyestuffs were made. We who led in the discovery of chemical dyes had seen the key industry which resulted from it pass into foreign hands, and others receive the birthright which belonged to us. He was glad, however, to say that the situation was altering, and that we were regaining the position which rightfully belonged to us. The most distressing feature of our time was our failure to link up scientific methods and discoveries with the public service; but perhaps the present serious state of many of our great industries and the necessity for seeking new methods and new sources of power would teach a lesson which adversity alone could teach.

Prof. H. E. Armstrong rightly remarked that Faraday was one of the greatest experimental philosophers the world had known. He began his career as a chemist; and the range of his chemical activity was astounding. As one of the earliest workers in organic chemistry he stood pre-eminent. He not only discovered benzene, but three of the five chlorides of carbon, and he was the first to study the sulphonic acids, a class of compound now of great technical importance. The discovery upon which they based that commemoration, that of benzene, would always rank as one of the most fundamental discoveries of chemistry. If not the hub of the organic section of the chemical industry, benzene was at least a major part of it. Benzene only acquired technical importance from 1856 onwards. An enormous amount of credit was due to Perkin, who not only discovered the first aniline colour, mauve, but founded the original dyestuff industry. Nothing that had happened since Faraday made his discovery would have given the philosopher greater pleasure than the advance of our knowledge of the origin of colour—a subject which once filled his mind. By some uncanny process, Faraday had prophesied what the X-rays were now justifying.

Addresses praising the work of Faraday were delivered by foreign and British scientists; and several men of scientific eminence were elected hon. members of the Royal Society.

The Earl of Balfour said they would have been neglectful of their duty if they had not asked the world to join in celebrating the memory of one of the greatest men in science, perhaps the greatest experimenter the world had produced. They were celebrating the centenary of what was the first of the great discoveries associated with the name of Michael Faraday. It was the first of a long series of discoveries which succeeded each other with almost bewildering rapidity. In the 'thirties, and in the years following in which some of these discoveries were made, there existed profound political discussion in which parties were bitterly divided in storms of political controversy. He had often thought how strange it would seem if people could be brought to realize that the quiet worker within the walls of that institution was having a greater effect on the development of civilization, the welfare of mankind, and the progress of commerce and knowledge than anything which was doubtless important in the disputes of politicians in the evolution of society. They might look where they would at the modern state of knowledge and industry, and they would see that almost all, if not absolutely all, the most striking developments which had happened either in the world of industrial production or scientific speculation were associated with the name of Faraday, and intimately connected with his discoveries. In the course of the last 25 years there had been the most amazing developments in the general conception of the physical universe in which our lot was cast. They were all intimately connected with the discoveries of Faraday. In regard to modern theories of electricity, of the constitution of the atom, and of the arrangement of the atom within the molecule, Faraday's discoveries had had the greatest effect, and constituted the most profound speculation ever made into the constitution of matter, which was now the glory and the astonishment of the age in which we lived. Broadly speaking, the fact remained that in the world of practice and the world of theory Faraday was one of the greatest builders the world had ever seen.

CELEBRATION BANQUET.

The Duke of Northumberland presided at a celebration banquet at the Hall of the Goldsmiths' Company. Scientists from all parts of the world were present, among them being Sir Alfred Mond, M.P., Mr. Milne Watson, Prof. Bone, Sir Dugald Clerk, and Mr. E. V. Evans.

The toast of "The Immortal Memory of Faraday, Chemist and Philosopher, Discoverer of Benzene," was submitted by the President, and acknowledged in silence.

Sir Alfred Mond, M.P., proposing the toast of "Chemical Science and Industrial Art," spoke of the far-reaching effects of scientific discovery on daily existence. Faraday, whom they were celebrating, was one of those outstanding men to whom science was not divided into fields, but was in itself one great field. If scientific knowledge were more general than it was to-day, our attitude in regard to the application of science to medicine, agriculture, industry, and, in fact, to everything concerning life, would be based on something better than observation, assumption, or conviction. Each new discovery opened a way for more fundamental and still greater knowledge. The progress of humanity was marked in each successive stage by its conquest over nature and its utilization of nature's boundless wealth. The future prosperity of the world, the solution of its economic difficulties, the security of its teeming millions, depended far more upon its scientific progress, upon its increased power to produce wealth by the application of scientific thought and method to its industrial problems, than to any other force of human effort.

It has been decided to award a medal, without regard to nationality, for outstanding achievements in relation to Faraday's discovery of benzene. The first recipient of the Centennial Medal is Mr. James Morton, of Carlisle and Grangemouth, in recognition of his work in developing and extending the manufacture of anthracene dyestuffs.

An interesting exhibition was arranged at the Science Museum, South Kensington, commemorating the centenary of the discovery of benzene by Faraday. Exhibits showed the importance of benzene to the synthetic dye industry, and illustrated the distillation of coal tar, from which benzene is obtained on a commercial scale.

LAUNCHING OF THE "FIREGLOW."

A new steamer, the "Fireglow," was launched for the Gas Light and Coke Company on Friday last, June 19, from the yard of Messrs. S. P. Austin & Son, Ltd., of Sunderland.

In responding to the toast of "Success to the 'Fireglow,'" proposed by Mr. W. H. Dugdale, Managing Director of the building firm, Mr. D. Milne Watson, Governor of the Gas Light and Coke Company, said that during the war his firm were forced to build or buy 18 vessels, 12 of which were lost. They now had eleven vessels, the "Fireglow" making the twelfth; and they were looking forward to the launch of yet another from that yard at an early date. These boats helped to carry coal for their great works in London to the extent of 1,200,000 tons a year, so they would see the important part that shipping played in the activities of the Company. He was glad to know, having regard to the depressed conditions on the Wear, that of the five ships now building on the Wear two of them were for his firm. Trade was in a serious state in this part of the country, and it was difficult to see any way out. He could not help feeling that they were constantly looking in the wrong direction for a solution. Everyone seemed to be looking to the Government for help—for the Government to wave a magic wand, or find a panacea to help the country out of its difficulties, and re-start trade. He believed that lower taxation and strict economy by the Government would do a great deal, but that the country would be saved only by its own exertions—in other words, by self-help. Unfortunately, this was not the fashion to-day. They were told that, if the Government would only start an electricity scheme and link-up super-stations throughout the country, they would have the country back on its legs again; unemployment would disappear, and the country would boom with trade. The gas undertakings were prepared to meet electricity, given a fair field, without fear. They could not believe that a big Government electricity scheme would achieve the desired object. He pointed out that the north-east coast had probably the most efficient electricity service in the country. The costs were very low—as low as they were to-day in Chicago. Yet the north-east coast was plunged into the deepest depression. Therefore electricity did not appear to be the means by which a revival of trade was to be brought about. He emphasized that in gas manufacture only 15 p.ct. of the heat value of the coal was lost, whereas in electricity 80 p.ct. was lost. There was also a suggestion for saving the country by the adoption of low-temperature carbonization. Up to the present it had not proved to be a commercial success. The idea existed that, if the Government spent ten millions of public money, trade would be restored; whereas it was not believed that ten millions of private money would achieve the same object. Both masters and men must face the situation; and if they conferred together, ultimately a solution would be found.

Success to the new ship was proposed by Mr. W. H. Dug

dale; and Sir John S. Hindley, of Messrs. Stephenson, Clarke, & Co., proposed the health of the builders and the engine builders, the North-Eastern Marine Engineering Company, Ltd. Mr. Dugdale and Mr. Adams responded for the respective firms.

The "Fireglow" has a length of 225 ft. and a breadth of 36 ft., and is designed to carry 1850 tons deadweight.

LONDON AND SOUTHERN DISTRICT JUNIOR GAS ASSOCIATION.

Visit to Cambridge.

On Saturday, June 20, the Association visited that remarkable town Cambridge, which is such a delightful mixture of the old world and the new. About 180 members and their ladies took part in this visit, which, thanks to the excellent arrangements made by the Cambridge University and Town Gas Light Company, and in particular by Mr. J. W. Auchterlonie, the Engineer and Manager, proved of unusual interest and enjoyment.

During the morning the members inspected the Cambridge Gas-Works.

DESCRIPTION OF WORKS.

The works consist of three retort houses. There is a horizontal house comprising ten beds of 8's, machine stoked by Jenkins De Brouwer machinery. The second house consists of inclined retorts—ten beds of 6's set at an angle of 32°. The third house is a new horizontal house which has just been completed. The settings, which were constructed by Messrs. Gibbons Bros., consist of eight beds of 8 retorts placed in four tiers of 2's; the size of the retorts being 24 in. by 15 in. by 22 ft. long. Cort's anti-dip pipes have been installed, and two 12-in. Parkinson & Cowan retort-house governors have been fitted on the foul mains. There are ascension pipes and hydraulic mains on each side of the house. This house is to be operated by the latest type of Jenkins De Brouwer charging and discharging machines; and the coke plant consists of a "D. B." coke conveyor discharging into a screening plant and reinforced concrete hoppers which will hold large and broken coke and screened and fine breeze.

Outside the house a new condenser has been erected of the horizontal cross-tube type by Messrs. W. C. Holmes & Co. From this the gas is taken by a 24-in. main to the exhausters. The exhausting plant consists of three sets comprising a new 300,000 c.ft. per hour exhauster, one of 80,000 c.ft. per hour, and a 100,000 c.ft. per hour twin set, all by Messrs. Bryan Donkin & Co.

The washing plant comprises a Holmes "P. & A." tar extractor, a Kirkham, Hulett, & Chandler centrifugal washer, and a Holmes horizontal brush washer. This plant has a capacity of 2 million c.ft. per day. An additional washing plant to deal with 3 million c.ft. per day is to be put down during the next few months.

The purifiers are situated in two distinct units which can be worked separately, the first house being the most modern. It contains four boxes 40 ft. by 30 ft. by 6 ft. deep. These are mounted upon a steel-framed structure, with brickwork enclosing three sides of the building. The boxes were constructed by Messrs. C. & W. Walker, Ltd., and the lids are fitted with Clapham "Eclipse" joints. The second house contains three boxes 30 ft. by 20 ft. by 4 ft. 6 in. deep, and three water-lute purifiers which are used as catch boxes.

There are two station meters of 80,000 and 50,000 c.ft. per hour respectively, made by Messrs. Parkinson & Cowan, as are also the station governors. There are two Humphreys & Glasgow blue water gas plants, the combined capacity of which is 1½ million c.ft. per day.

The present holder capacity is somewhat limited, being only 1,700,000 c.ft. of town gas and 300,000 c.ft. of blue water gas. A new gasholder tank is in course of construction, and this will accommodate a holder of 3 million c.ft. capacity. The tank when finished will be 100 ft. in diameter by 38 ft. deep. It is being constructed by Messrs. R. Robinson & Co., and is of mass concrete 4 ft. thick at the base continuing for 17 ft. and tapering to 2 ft. 3 in. at the ground level. Steel bars 4½ in. by ⅝ in. are placed round the tank at 4 ft. 6 in. centres embedded in the wall; the first ring being 9 ft. from the base. The proposed holder is to be a three-lift column-guided one.

It was found that a retaining wall was necessary along the boundary of the works and the River Cam haulingway, to support the gasholder tank. This wall has just been completed, and consists of mass concrete panels to which piers were built afterwards. The height of the wall is 11 ft. above ground level, and the thickness of the piers is 1 ft 3 in. and the width 1 ft. 6 in. The total length of this wall is 412 ft. 6 in. A ½-in. expansion joint has been left at the ends of each panel.

The boiler house contains three Lancashire boilers, 30 ft. by 8 ft. 6 in., by Messrs. John Thompson, Ltd., fitted with Goodrich & Hamlyn furnaces. The power house contains three steam electric generating sets of 50, 75, and 175 KW. capacity, by Messrs. Allen, of Bedford.

Over the power house a water softening plant is situated, and a deep well pump supplies water to a tank over the water softener, which forms the roof of the power house. This tank contains 25,000 gallons, and supplies all the water to the works.

An electric boosting plant of 300,000 c.ft. per hour was put down in 1923, and this is used for boosting gas from No. 2 holder on to the station governor, the excess being driven into No. 4 holder.

Practically the whole of the tar produced is dehydrated and used for tar spraying by the Local Authorities.

The liquor is only worked-up to 10-oz. strength at present, and is conveyed by barges to King's Lynn, where it is used for sulphate of ammonia manufacture.

Naphthalene troubles are not experienced at Cambridge, no doubt due to the use of a Parkinson vaporizer.

LUNCHEON.

After the inspection the members were conveyed to the Lion Hotel, where, with their ladies, they were the guests at luncheon of the Directors of the Gas Company. After the honouring of the Loyal Toast,

The Rev. E. C. PEARCE, D.D. (Master of Corpus Christi College, and Vice-Chairman of the Cambridge University and Town Gas Light Company), who presided, extended, on behalf of the Directors of the Company, a hearty welcome to the Association. Cambridge, he said, was an ancient town; but the Directorate of the Gas Company were anxious that this adjective should not apply to the gas-works. The members, during the morning, had been able to see what steps were being taken to render the works thoroughly modern.

Mr. W. NEWTON BOOTH (President of the Association) said that he had been asked to perform, on behalf of the Association, what was a pleasant but rather sad duty. This was to ask Mr. W. H. Noble, Assistant Hon. Secretary of the Association, to accept an illuminated address in recognition of the valuable work he had so willingly done for the benefit of the Association. Mr. Noble was leaving the country for the United States of America. They were all very grateful to him, and hoped that in his new sphere he would not forget the Old Country.

Mr. NOBLE, in thanking the Association for the address, which, he said, he would always value very highly, gave them his assurance that he would never forget the happy period he had spent with the Association.

Mr. NEWTON BOOTH then thanked the Directors of the Cambridge Gas Company, and Mr. Auchterlonie, for the splendid interest and entertainment which they had provided. As the Chairman had remarked, Cambridge was an ancient town; but the gas-works were anything but ancient, and reflected great credit on the Directorate and engineering staff. The members of the Association would long remember the enjoyable and useful visit.

Mr. W. L. WESTBROOK proposed, and Mr. A. BROADBENT seconded, a vote of thanks to the Directors of the Cambridge Gas Company, and to Mr. Auchterlonie.

This was carried with acclamation.

The Rev. PEARCE, in reply, voiced the regret of the Chairman of the Company (Mr. Parker) at being unable to meet the Association. As for the arrangements which had been made for their visit, the credit was due to Mr. Auchterlonie.

Mr. AUCHTERLONIE said that he had a warm corner in his heart for the London and Southern District Juniors, and was very pleased to offer them a welcome.

During the afternoon the party visited some of the Colleges. The weather was perfect, and the "backs"—always charming—were more delightful than usual.

A very successful visit was brought to a close by tea, at the invitation of the Chairman and Directors of the Gas Company, at the Lion Hotel.

Coke-Oven Gas for Town Supply.

The Gas Companies of Albany, Schenectady, Troy, Cohoes, Rensselaer, and Watervliet have contracted to take between them the entire supply of gas from the coke ovens of the Hudson Valley Coke and Products Corporation at Troy (N.Y.), which are expected to be in operation some time next autumn. Approximately $6,000,000 will be the cost of the plant, which is to occupy an area of about 50 acres. Ultimately there will be three batteries of 55 ovens each, though at the moment only one unit of ovens is under construction. Thus the production at first will be 1000 tons of coke a day, and 5 million c.ft. of gas. When more gas is needed to serve the cities dependent upon the plant, there are blue water-gas generators which may be put into commission to furnish fuel for the ovens; while if the total production of the ovens is not enough, carburetted water gas sets are provided to supplement the capacity. The plant is planned to be elastic enough to meet any peak loads that may arise in the territory.

Visit to Derby.—Mr. Ferguson Bell writes to say that, before leaving for London on the Monday in Institution week, he placed his Assistant Engineer, Mr. J. P. M'Crae, in charge of the arrangements for the visit to Derby. Mr. M'Crae, with numerous other members of the staff of the Derby Gas Light and Coke Company, worked with enthusiasm, and to them much credit is due for the success of the visit.

THE LEEDS AND NORTHRUP POTENTIOMETER PYROMETER.

The following description of this useful piece of apparatus is based on particulars supplied by the Integra Company, Ltd., of Birmingham, who are the British representatives of the Leeds and Northrup Company.

It is becoming more and more recognized that the potentiometer pyrometer presents many practical advantages. For instance, the readings are entirely unaffected by the resistance of the thermocouples, lead wires, switches, or any contacts in the circuits. The readings, therefore, are unaffected by the length and cross-section of the thermocouples and lead wires. This is an exclusive feature of the potentiometer. There is complete and accurate compensation for the temperature of the cold junction. No accessory devices such as thermostats, buried cold junctions, &c., are required. Changes in the temperature of the instrument itself do not affect the readings. The potentiometer is inherently constant in its accuracy. Two elements, and two only, are required to be constant. One of these is the resistance of manganin, which has been proved to remain constant to 1/25 p.ct. The other is the voltage of the Weston standard cell. This also has remained constant to 1/25 p.ct. while in use for more than twenty years. Pyrometers seldom require an accurary better than $\frac{1}{4}$ p.ct. (5° in 2000°).

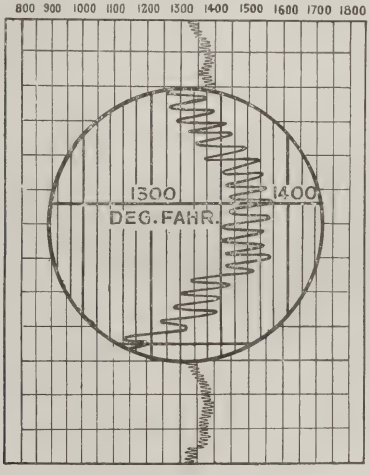
Owing to their principle, and in spite of their great accuracy, the potentiometer recorders are robust machines, for the only sensitive moving part in the instrument is the galvanometer, which is not calibrated, but serves merely as a current detector. A small electric motor with automatic governor absorbs the frictions, drives the recording mechanism (switching, printing, unrolling of the chart), and acts as a servomotor to set right alternatively the resistance and the slide wire so far as the galvanometer needle does not stand motionless. This motor has a surplus of power which is available to operate various signal devices without affecting in the least the sensitivity of the apparatus.

Application to the Gas Industry.

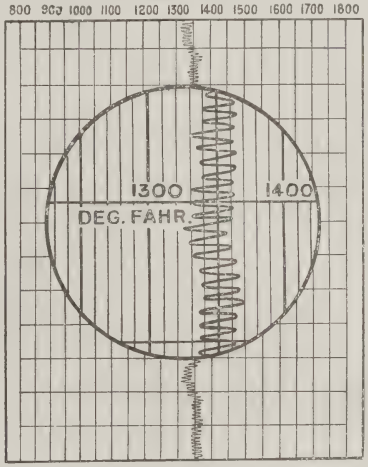
Gas engineers are agreed that present-day oils require close temperature control. Furthermore, as the specification and sale price are set by law or contract, profits depend almost entirely upon savings effected by skilful operation and the elimination of all waste. Take an average present-day oil of about 31° Bé. Best gasification is obtained, let us say, at about 1400° Fahr. in the superheater. Now, a low temperature will fill the seal pots with partly cracked oil and not a little undesirable tar. On the other hand, a high temperature brings excess naphthalene and lamp black to emulsify in the wash box. Either way ends in costly trouble and an inferior product. Consequently, to avoid all these difficulties, and keep within the profit zone, it is essential to use accurate temperature measuring equipment. The "L & N" signalling recorder is, in this way, a great help to the gas-maker. In addition to the graphic record, this apparatus gives visual signals with electric lights—red, white, and blue—high, correct, and low, respectively. Moreover, a deviation indicator gives on a dial the number of degrees one is away from the correct temperature. The recorder may be placed at any distance from the superheater—for instance, on a table in the engineer's office. The deviation indicator and signal lamp attachments are, of course, before the eyes of the operator. These flashing signals are ideal for attracting his attention. As a result, when the temperature starts to change, it will be noticed immediately, and can be restored promptly. Without the signal lights, the change would continue until the gas-maker happened to look at the instrument, and considerable trouble might result from even a short delay.

The "L & N" continuous charts reproduced here were made from a set that had just been equipped with a signalling recorder. [It may be mentioned that the diagrams are recorded by the apparatus in red ink.] Though taken only two weeks apart, marked improvement is shown. These two charts are conservative in picturing the gains to be made by the use of accurate temperature guides. Many sets are operating with greater variation than the 120° Fahr. shown on the chart to the left; but with the help of a signal-light recorder, they can be held within a range of 50° Fahr. or better.

To terminate this article, we would mention that for a certain type of water gas machine, the Leeds and Northup Company manufacture a master temperature controller which automatically maintains the temperature constancy in the superheater.



This record was made immediately after the recorder was connected, but without reference to it as an operating guide. Although an attempt was made to hold the average temperature constant, it varies from 1300° to 1420° Fahr., a variation 120° Fahr.



This record was made after two weeks' use of the "L & N" signal-light recorder as an operating guide. The average temperature has been held between 1325° and 1375° Fahr., a variation of only 50° Fahr. The sections of the charts in the circles are full size.

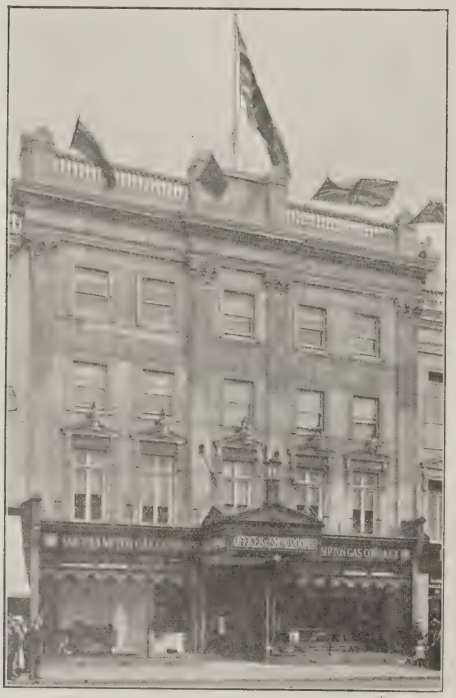
Cast-Iron Research.—The Council of the British Cast-Iron Research Association have recently extended the research programme by arranging for an investigation on the influence of silicon, manganese, and phosphorus on the formation of graphite in cast iron, to be conducted by Mr. M. L. Becker, M.Sc., at the University of Manchester.

Paint on Gas-Works.—Mr. Jacob B. Jones, Superintendent and Treasurer of the Bridgeton (N.J.) Gas Light Company, has been discussing in the pages of the "Gas Age-Record" the value and importance of the attractive gas-works. One matter to which he refers is the painting of gasholders. The management, he points out, is interested in getting the best covering that it can, for the longest space of time, at the lowest cost. The neighbours, on the other hand, are not interested in this at all; they want to know what colour it is going to be. In a case he quotes, the quality of the paint was decided upon, but several test sheets were prepared in order to show the different colours. Then invitations were sent out to all the neighbouring owners; and it being a residential neighbourhood, the subsequent conference was largely attended. It was agreed that a decision by a majority of those present should be considered final; and strange as it may seem, the decision was unanimous. Pursuing his subject, Mr. Jones says: If you really want to make the gas plant an attractive place to visit, aluminium paint on condensers, scrubbers, pipelines, and general plant equipment may be well worth your consideration.

SOUTHAMPTON'S NEWEST ATTRACTION.

Ideal Working Conditions and Service to Consumers.

Southampton is a beautiful town, from both natural and architectural points of view; and one of its features is an excellent shopping area in the main thoroughfare, to which was last week added a still further attraction in the form of new offices and showrooms for the Southampton Gaslight and Coke Company. The continuous growth of the Company's business having rendered the old premises in Ogle Road insufficient for their purpose, and the desirability having been recognized of coming out into the busiest street (though, as a matter of fact, Ogle Road itself turns out of the main thoroughfare), Mr. J. R. H. Jacobs, F.C.I.S., F.S.A.A., the Company's energetic General Manager and Secretary, looked about him, and was fortunate enough in due time to find what he wanted. During the war an hotel in Above Bar—a stretch of the long straight business thoroughfare to which reference has already been made—was purchased by the Y.M.C.A. for use as a hostel, and therefore the licence was given up. When its use for this purpose came to an end, it was in the market; and it is a portion of this former hotel that the Gas Company have acquired. Excellently indeed have the Architect (Mr. Harry J. Weston)



New Showrooms at Southampton.

and his partner, Mr. Gordon L. Thorne, under whose supervision the work was carried out, adapted the site to its new use.

THE GROUND FLOOR.

The first impression that is conveyed to the mind of the visitor is one of "roominess." There can be no crowding here, either of staff or of apparatus; and it will be possible to accommodate simultaneously any reasonable number of consumers or prospective customers. Thus has one of the cardinal points to be aimed at been secured.

The windows—one on either side of the main entrance—are, of course, large; and it is intended to maintain interest on the part of the general public by changing the contents of one window every week, so as to give each display a fortnight's run. For the opening, two excellent settings had been arranged, based on British Commercial Gas Association suggestions for window displays, with Mr. Jacobs's additions. "After the game, a refreshing bath," was the wording to one tableau, which showed a tennis court, and one of the players proceeding to a tempting gas-equipped bath. In the other window was a street scene, picturing mainlaying operations, with the watchman by his coke fire, and wording drawing attention to the advantages of this form of solid smokeless fuel. Lengths of main lying in the foreground had painted on them the names of villages on the borders of the Company's district, so that the people of Southampton might know exactly the extent of the area of supply. The names of these villages were Botley, Hedge End, Lyndhurst, Chandlersford, Hythe, and Fawley, some of which already enjoy, while others will shortly, the benefits of the Company's service. Readers will have noted in last week's "JOURNAL" the report of an inquiry by Mr. H. C. Honey into an application by the Company to the Board of Trade for a Special Order having for its object, among other things, to extend the area of supply. Each window is beautifully lighted by a 1500 C.P. row of inverted incandescent gas lamps designed by Mr. J. W. Lofts, of Messrs. William Sugg & Co., to meet the special circumstances. They are on distance control. A channel running the length of the window above the lights takes the products of combustion into a flue leading into the chimney. This installation is proof of the efficacy of gas for the lighting of shop windows.

The front showroom, which is 46 ft. wide and 68 ft. long, has been fitted up in a highly attractive manner, and in accordance with the most modern ideas. Everything is good, and of a type completely suitable for the purpose which it is intended to fulfil. In the centre, pylons are being arranged for the effective display of gas fires, as are to be seen in the British Empire Gas Exhibit, while on one side are arranged a model working kitchen and a bathroom—the latest forms of apparatus for cooking and water heating being demonstrated. In connection with the bathroom, one point may be specially mentioned. The Company have recognized, as have others, that, in connection with certain housing schemes, where the bath is provided on the ground floor, there is an advantage, from the builder's point of view, in providing one heating medium for both wash-copper and bath. They therefore show a gas-heated copper, fitted with a syphon arrangement of their own design, by means of which practically the whole of the heated contents

Showing Model Bathroom.

of the copper can be transferred to the bath. To achieve this object no increase in the length of the legs of the wash-copper has been found necessary. Of the lighting of the showroom, by Evered's fittings, all having switches, no more need be said than that it is fully in harmony with the handsome surroundings. The oak panelling of the walls and the teak-block floor are in keeping with the predominant idea—which has been to represent gas appliances in a homely setting.

No one will enter the showroom without giving attention to a fine display of fruit and vegetables bottled and crystallized. This is the work of Miss Baverstock, the Company's Lady Demonstrator, and many readers will remember looking—with feelings of something more than admiration—at the glass case containing these tempting specimens, when it was on view last year in the British Empire Gas Exhibit. As a matter of fact, the Company, at the instance of the Government, started this work for the forces during the war; and finding there was a demand among the consumers, they have continued it since. Consumers having a stock of fruit or vegetables which they desire bottled may apply to the Company; and it is done for them in their own houses—for which service a small charge is made.

At the rear of the showroom is the general office, 36 ft. wide and 68 ft. long, with a counter for the public in front, separated from the showroom by an oak and glazed screen. There is accommodation here for a large staff to work in the greatest comfort. The top lighting of this general office is very striking; and first-rate artificial illumination is provided by Sugg semi-indirect lamps, on distance control. On one side are several private offices, and a comfortable waiting room for the use of the public.

At the back are other offices, stores, and lavatories, and a staff entrance in Vincent's Walk, with accommodation for bicycles in the yard adjoining.

GROUND FLOOR, SHOWING ENTRANCE TO OFFICES.

Other Floors.

The old hotel staircase, although it was tucked-away in a dark corner, when brought to light by the removal of the surrounding walls, was found (under many coatings of paint) to be rather a fine piece of work in solid mahogany; and this has been retained and made to fit-in with the alterations. An electric lift, in addition to the staircase, serves all floors.

On the first floor the old hotel rooms have been converted into offices, and a new oak-panelled Board-room, 20 ft. wide and 38 ft. long, provided in the rear, with access to the flat roof over the general office below. This has been arranged as a roof garden. The second floor has been fitted-up as offices, &c.; while the third floor provides spacious accommodation for the two caretakers. The old cellars of the hotel have been adapted for use as strong rooms and stores.

An important item is the conference hall, with direct access to Vincent's Walk. This is 24 ft. wide and 36 ft. long; and it is intended that it shall also be for the social use of the Company's staff. In order that it may be perfectly applicable to both these purposes, it is provided with a sliding platform, which can be removed from view when not required.

A House-Warming.

From what has been said, it will have been seen that the Southampton Gas Company have taken a step which will inevitably lead to increased business—firstly, by making the working conditions ideal, so that the staff shall give of their best; and, secondly, by affording ample facilities to the public to acquire a perfect understanding of the multifarious uses and advantages of gas. The new venture received an excellent send-off last Thursday, with the formal opening. The Chairman of the Company (Mr. J. C. Moberly, M.A.) presented the Mayor of Southampton with the necessary key, and his Worship the Mayor (Alderman T. M'Donnell, J.P.) then unlocked the door and declared the showroom and offices open. The word "formal" has been mentioned, but in reality there was nothing whatever that was formal about the occasion. Members of the Corporation, Directors, and officers of the Company, with a few visitors, made up a "family party," the most appropriate description of which perhaps would be "friendly relations." Exactly what is meant by this will be gathered by readers who noticed in last week's "Journal" that, in the report of the proceedings before the Board of Trade, regarding the Company's application for a Special Order, the significant statement was made that objections were raised by the Southampton Corporation, but certain amendments to the Order were agreed between the Company and the Corporation.

Following the opening, about fifty sat down to luncheon in the conference room; and in the speeches which followed, the existence of this spirit of friendliness was emphasized, and was recognized as being mutually advantageous. The Chairman presided, and was supported by the following members of the Board: Sir H. W. Russell Bencraft, J.P. (Deputy Chairman), Mr. A. W. Oke, Mr. R. C. S. Pearce, Mr. Joseph Cash, and Col. E. K. Perkins, C.B.E., M.P. The Auditors were there—Mr. F. J. Burnett, F.S.A.A., and Mr. A. H. Cobbold. As to the officials, in addition to Mr. Jacobs, there were present Mr. F. Durkin (Resident Engineer and Man-

ANOTHER VIEW OF THE GROUND FLOOR.

ager), Mr. F. Lewis (Accountant), Mr. E. Dunbar (Assistant Engineer), and Mr. F. Pitman (Cashier). The guests included the Mayor, the Deputy Mayor (Alderman W. Mouland), the Sheriff (Councillor J. E. Silverman), the Town Clerk (Sir Richard Linthorne, O.B.E.), Mr. F. C. Carter (President of the Southampton Chamber of Commerce), Mr. H. C. Head (Winchester), Mr. T. Carmichael (Portsmouth), Mr. F. J Falkner (Romsey), Mr. Charles Clare, and Mr. R. Stephenson Clarke. Both Mr. Clare and Mr. Stephenson Clarke were particularly welcomed, because the firms of Messrs. Fletcher, Russell, & Co., and Messrs. Stephenson Clarke & Co. have for very many years had particularly close business relations with the Southampton Gas Company. Mr. F. W. Goodenough was to have been present, and to have responded to a toast, but to the great regret of all an urgent business engagement kept him away. Councillor F. R. Brown (the Chairman of the Municipal Electricity Department) would have been there with the Electrical Engineer, but both were in Brighton at a conference. Mr. Brown, however, wrote: "We both appreciate the good feeling existing between your Company and our undertaking."

Sir RUSSELL BENCRAFT (after the honouring of the Loyal Toast) proposed "Our Guests," and remarked that the Company worked in great amity with the Corporation. He also paid well-deserved tribute to Mr. Jacobs and his efficient staff.

Mr. H. C. HEAD, responding, congratulated both the Company and the town on the very fine premises they had seen opened that day. A gas company should, he said, have adequate showrooms and offices. Indeed, such an undertaking would not be doing its duty to the town it served if it did not provide headquarters worthy of a commodity that was supplied, for one purpose or another, to probably 95 p.ct. of the inhabitants. In many places the public service rendered by the gas company to the community was not sufficiently recognized. He felt that in their new showrooms and offices the Southampton Gas Company were giving an excellent lead to other undertakings in the district. In these days no business could be successfully conducted without publicity; but it should always be remembered that a satisfied consumer was the best form of advertisement. They wished the Company all success and prosperity in their new home.

The MAYOR submitted the toast of "The Southampton Gas Company," and spoke of the cordial relations existing between the Company and the Corporation. The Company were at present seeking powers to extend their area. The Corporation might have contested the Special Order step by step and line by line, and so set up a big fight; but instead of this he himself with the Town Clerk met the representatives of the Company at the offices of the Parliamentary Agent, and in twenty minutes, in the most cordial manner, every little objection was removed. [Applause.] The Corporation were determined that, as far as lay in their power, all difficulties that might arise should be solved by friendly deliberation. The Company's undertaking was one of the largest and best organized industries in the town, and was deserving of all consideration.

Mr. MOBERLY, in response, remarked that during the 35 years he had had a seat on the Board he had been amazed at the progress of the industry, and at the ignorance of those who persisted in going about saying that "gas was on the wane." Nothing could be farther from the truth; for the industry had never been in a stronger position than it occupied to-day. The Company were at the moment increasing their works to meet the demands for gas, and were seeking an Order to extend the area, in order to satisfy the clamour by neighbouring parishes for a supply. He was confident that amicable relations would continue so long as they had with them their genial and tactful General Manager, Mr. Jacobs. The Directors felt that they owed those fine premises, too, to the energy, enterprise, and ability of Mr. Jacobs, in conjunction with his old friend Mr. Harry J. Weston, who had acted as Architect.

The staff were not forgotten, for later in the day about 130 were the guests of the Company at tea in the new premises.

On the following afternoon about 300 of the stockholders inspected the new premises, and were afterwards entertained at tea.

Benzole Sales in Germany.

In the current issue of the "Iron and Coal Trades Review" it is mentioned that, in order to guard against the dangers arising from irregular Franco-Belgian sales, the Bochum Syndicate of Germany have initiated steps with a view to bringing about an understanding with the French and Belgian benzole producers. The proposals are said to have been favourably received and promise to lead to satisfactory results. The first thing required is the creation of firm syndicates in France and Belgium. The German Syndicate will then be able to place their experience in propaganda work and sale policy at the disposal of these syndicates, and pave the way for the increase of deliveries in both those countries. At the same time efforts will be made to lead the benzole finding its way into Germany into a uniform channel—that is, through the organization of the Benzol Syndicate, in order to check in this way the present sale of foreign benzole in Germany at low prices. It is also proposed to work in the direction of bringing about a stabilization in prices by the conclusion of an agreement under which, in the event of a shortage of benzole arising in one or other of the interested countries, compensation deliveries would be supplied by the country having a surplus.

YORKSHIRE JUNIOR GAS ASSOCIATION.

Presentation to Late Secretary.

On the occasion of the June meeting of the Yorkshire Junior Gas Association, during a visit to the works of the Wakefield Gas Company, a presentation was made to Mr. F. A. C. Pykett, the late Hon. Secretary of the Association, now Distribution Superintendent at Lancaster. Mr. Pykett was Hon. Secretary for three years.

The presentation, which took the form of a handsome Jacobean oak bureau bookcase, subscribed for by the members of the Association, was made by Mr. E. Gillett, the President of the Association, who referred to Mr. Pykett's three years' excellent and enthusiastic service. Mr. Pykett had always given his best to the Association, both before and during his Secretaryship, and they all hoped he would find his new sphere of activity pleasant and profitable, and that he would long be spared to enjoy the gift.

Mr. Pykett, responding, said he had done what he could for the Association because he felt that it was the duty of every member to put in the best of which he was capable on behalf of all, whether it was in some definite office or in the more modest position of an ordinary member. He thanked the officers and Council, and the members generally, for their support during his Secretaryship, and for their generous gift.

THE "ABBIRKO" SUCTION SERVICE CLEANSER.

Gas engineers are agreed that it is preferable to withdraw the material forming the stoppage in a service pipe, rather than force it into the main. The advantages are obvious, and include the following:

The stoppage cannot recur by the same material again passing into the service pipe.

The stoppage cannot be aggravated by forcing more loose matter into the elbow or bend at the junction to the main.

The area of the main is not reduced by repeated clearing of the services.

The material causing the stoppage may be examined.

To obtain the above results, it is essential that a very powerful vacuum be obtained, and maintained throughout withdrawal; and to be effective this suction should be applied suddenly, in order to give the necessary shock action to loosen any solid accumulation. In addition the apparatus should be reasonably portable. The above ideals are admirably carried out with the "Abbirko" suction cleanser, manufactured by Messrs. Abbott, Birks, & Co., of No. 113, Newington Causeway, London, S.E. 1. The energy required is obtained by a storage of air pressure up to 300 lbs. per sq. in. in their Renrut No. 34 high-pressure cleanser, and released into the suction service cleanser by means of a patent instantaneous piston release valve. This operates a piston which in turn suddenly extends a collapsible reinforced vulcanized bag, causing a powerful suction. The material withdrawn is intercepted by an easily detachable filter. The whole is portable, strongly constructed of best materials, and most reliable in action. This cleanser, it may be mentioned, has cleared solid-blocked services 18 ft. long by 1½ in. diameter, containing wet rust, naphthalene, and other matter.

"Metallon"—A New Anti-Corrosive.

Corrosion and the various processes for its prevention have always interested gas engineers. We hear that a new process has now been placed upon the market whereby a protective metal film can be placed on iron, &c., cold, with a brush in a similar manner to ordinary paint. This material, known as "Metallon," forms a protective couple with the underlying iron. No pickling process is necessary, consequently the metal is not weakened and an alloy is not formed on the surface of the underlying material. The simplicity of application also allows repairs to be carried out *in situ* at a minimum of expense and disorganization. Another interesting property of "Metallon" is that it will not peel, blister, or lose colour up to the melting-point of the metal from which it is composed. Thus, aluminium "Metallon" will maintain its appearance and protection up to 659° C., or 1220° Fahr. The key obtained by the material is exceptionally good; and we understand that it will adhere to a glass surface with such firmness that it is impossible to remove by any ordinary means. The possibility of satisfactorily metal-coating asbestos flue pipes—say, with copper—for rendering their appearance more attractive has frequently been discussed by both the gas industry and the various makers concerned. It seems possible that "Metallon" would meet this demand cheaply and effectively. The havoc of corrosion is estimated to cost this country £100,000,000 per annum. We hope that this new material may be able to reduce this expenditure. In any case, in view of the inventor's claims, it would seem to be worthy of investigation by the gas industry.

NORTH OF ENGLAND GAS MANAGERS' ASSOCIATION.

Visit to the Works of the Consett Iron Company, Ltd.

The Association were fortunate enough to be the guests, on Wednesday last, June 17, of the Consett Iron Company, Ltd., of Consett, Co. Durham. Among the most enterprising of north-country firms, the Company control collieries, coke-ovens, brick works, blast-furnaces, and up-to-date steel works.

It was to inspect the silica brick works and the Wilputte coking plant that the visit was arranged—the former being claimed to be the most up-to-date in the country, if not in the world, and the latter being the only one of its kind in the Kingdom.

The Company are past masters at entertaining in this way. They have plenty of good things to show, they show them to the best advantage, and under cross-examination they display frankness and patience in explanation which satisfy even the most curious. Thus the visit was made most enjoyable, and from the points of view of both interest and instruction it was acclaimed a great success.

The party, which included the President, Mr. W. W. Atley, of Stockton, and the Hon. Secretary and Treasurer, Mr. Norman S. Cox, of Sunderland, numbered between 45 and 50. The majority made the journey to Consett by chars-a-bancs, through the charming scenery of the Derwent Valley, which always surprises those who imagine that the county of Durham is composed exclusively of pitheads, slag heaps, and unsightly mining villages. Fortunately, both for the journey of about an hour, and for the inspection, the weather was fine.

Arrived at the Templetown Brick Works—the first objective of the visit—the members were met by Mr. E. J. George, General Manager of the Company, and Mr. A. H. Middleton, Superintendent of the Coke and Brick Works, and other officials, who, without delay, divided the party into groups, and began personally conducted tours of the works.

The Templetown Brick Works.

A short description of the works was given in the "Journal" on the occasion of the visit last autumn of the Coke-Oven Managers' Association ["Journal," Oct. 22, 1924]. In view of the great interest and admiration displayed by the Gas Managers on the present occasion, some further details of the plant may well be recorded.

The works are devoted entirely to the manufacture of silica refractories, the raw material for which is obtained from a large royalty, containing an excellent quality of ganister, situated within a few miles of the works. The rock undergoes a preliminary sorting at the quarries, and is then brought to a storage yard at the works, where washing and further sorting are performed. Constant supervision and testing of the material in all stages of manufacture, from the raw to the finished product, ensure the maintenance of the requisite quality, and the selection of the ganister best suited to each particular purpose. Research and routine tests are carried out under ideal conditions in a splendidly equipped and up-to-date laboratory, which was one of the first objects of interest to be inspected.

Crushing, Weighing, and Mixing.

A swinging-jaw crusher, capable of dealing with 12-in. cubes, reduces the ganister to 3-in. size. The crushings are then elevated and further reduced to 1-in. size by a similar machine. The material is next automatically fed into a gravity-bucket conveyor, which distributes it to weighing pans. Automatic discharging of the buckets and weighing are accomplished by a very interesting device. The buckets are tipped by gear which goes out of action when a weighing pan has received the requisite weight of material, and re-engages when the pan has been emptied.

The fine crushing is accomplished, with the addition of a carefully measured quantity of milk of lime, in either of two mills of the revolving-bottom type; the period of grinding varying according to the use for which the finished material is required. The crushing weights, and also the weight of the charge ground, can likewise be varied to suit the ultimate product. A normal amount dealt with at one charge is about 18 cwt. An automatic tipping device delivers the silica mud to tipping bogies in which it is conveyed to hoppers, which supply the moulding tables.

The Moulding Process.

All moulding is done by hand on steel pallets; the Company not having discovered any machine moulding process which can be relied upon to give the accuracy of size and shape which they guarantee. Steel moulds with removable sides are used, made with the greatest care in the Company's own works. A very large variety of shapes is kept in stock, but special orders receive prompt attention. The moulders' work is very fascinating to watch, and the dexterity of touch in removing the moulds after beating the mud into them is remarkable. The ordinary bricks are moulded six at a time, and other shapes one or more according to size.

THE LABORATORY, TEMPLETOWN BRICK WORKS.

Drying the Shapes.

The shapes on their pallets are then loaded on to rack cars, on which they pass through a Proctor drying tunnel. This consists of a chamber 50 ft. long by 20 ft. wide by 6 ft. 6 in. high. In it are three distinct temperature zones, not separated from one another in any way, but produced by the arrangement and disposition of the dry-air inlet, the moist-air outlet, and a series of fans and heating coils. The temperature of the first zone is approximately 130° Fahr., and here the shapes remain long enough to be thoroughly heated through. The second and third zones are at about 145° and 205° respectively, and, in the whole process, moisture content is reduced from about 14 p.ct. to 0·09 p.ct. In the case of ordinary bricks, this takes about eight hours. Naturally the larger shapes require a longer period, and this is provided for in that three sets of rails run through the tunnel, on each of which a different rate of progress can be maintained. Eight cars can stand on each rail, the total capacity of the dryer being 14,976 bricks. As each car of moist shapes is fed in, a car of dried ones is discharged at the other end.

By this system, the shapes are dried in a continuously circulating atmosphere, humid in the preliminary stages, and gradually increasing in temperature. Heat is applied evenly to all surfaces, and unwanted stresses are not set up by the exterior drying before the heat reaches the interior—a most important consideration.

THE DRYING TUNNEL.

Burning.

Eight kilns are available for burning, each having a capacity of 100,000 standard bricks, or over 300 tons of material. The operation of stacking occupies more than three days, and great care must, of course, be taken so to arrange the shapes that there is sufficient space everywhere for expansion. The heating-up takes 12 to 14 days, a temperature of at least 1500° C. being attained. The kilns are then sealed, and cooling is by radiation only, the entire operation occupying four to five weeks.

The "set" material is then stored in dry sheds, where a rigorous inspection for size and soundness is made before dispatch. The running of railway sidings into the sheds considerably facilitates loading operations.

Mention of the careful control of every detail of the process has already been made. This is a feature to which the Company attach the greatest importance, and certainly all those present agreed that, judging from appearances, the finished products left nothing to be desired. The Company are large consumers of their own refractories in iron and steel works, and in their coking plant, so that the materials are under continuous test on the spot under actual working conditions. The lay-out of the works is admirably conceived, and the impression gained is one of ample space, smooth and expeditious working, and the maximum of consideration for the workers engaged.

The Company state that they have sold over 20,000 ft. of silica retorts, both vertical and horizontal, which are giving satisfaction in every case. The carbonizing time has been reduced by 20 to 25 p.ct., as compared with fireclay and semi-siliceous retort material, without any additional cost in heating the settings. In other words, this means that a works changing over to straight silica material as replacements become necessary would have its throughput increased by 20 to 25 p.ct. without further capital expenditure in putting-down more settings.

The Fell Coke Works.

A few minutes by road took the party to the Wilputte coke-oven plant, which is conveniently situated near the blast furnaces and the steel works, which are intended, when in full work, to be the chief consumers of the coke and surplus gas. A general description of the works was given in the "Journal" for Oct. 22 last, p. 237, to which reference may be made. The gas engineers on this occasion evinced considerable interest in the sister industry of coke making.

One of the chief centres of interest was the carefully controlled and efficient arrangement for heating the settings, which, of course, is entirely by their own gas. Every flue has its own regenerator, and the ovens are heated from both sides, there being 15 vertical flues on the coke side, and 13 on the ram side. Gas burns on one side in the vertical flues, and the products of combustion pass along a horizontal flue at the top and down corresponding flues on the other side, and through the regenerator. After half-an-hour, the process is reversed, and air is then drawn through the heated regenerator for the combustion of the gas which now heats the works and the regenerator on the other side.

The change-over is entirely automatic, and is worked by special gear situated near the meter and chart room, where the operations of the whole plant can be watched and controlled. An ordinary clock makes and breaks electrical contacts at the required intervals for reversing the flue circuits. A small pilot motor drives a commutator shaft, which is furnished with contacts, and these start and stop the change-over motors in proper turn. First of all a 5-h.p. motor comes into action and shuts-off the gas on one side of the battery. About 15 second later another motor reverses the air and waste-heat valves and dampers, and after 15 seconds more a third motor opens the gas cocks on the other side.

Considerable interest was displayed in seeing the pushing of the coke—an operation expeditiously performed for the size of charges. These are of slightly over 11 tons of coal per oven, giving a coke yield of 85 p.ct. for a carbonizing period of 15½ hours. The arrangements for quenching, elevating to the screens, and screening of the coke were all much admired, and the whole process and lay-out of the plant were generally agreed to be full of interest.

The Consett Company's Hospitality.

After a thorough inspection of the coking plant, an adjournment was made to St. Aidan's Hall, where the Consett Iron Company entertained the members at tea, Mr. E. J. George being in the chair.

Time was short for speech making, as many of the members had far to go after returning to Newcastle.

Mr. E. J. George, in a few words, said how glad his Company had been to welcome the Association and show them whatever there was to see.

The President, in returning thanks for the great hospitality offered, said that the visit, in addition to being of interest, had been also an education to most of them. Most striking to members of the gas industry were the carbonizing speeds attained, and the economy of space effected by the Wilputte plant.

Mr. George briefly returned the thanks of the Company, and

Mr. A. H. Middleton added how pleased he and his staff had been to receive the Association at their works. If any of them had not seen as much as they wanted, he would be only too pleased to receive them at any time in twos or threes, and go into more detail. He announced, amid general approval, that he had accepted an invitation from the President to read a paper at the October meeting of the Association, so that he would not at present say anything of technical matters.

With this the proceedings terminated.

Central Station Voltages and Charges.—Messrs. S. Rentell & Co., Ltd., of No. 36, Maiden Lane, W.C. 2, have published a little volume, at 1s. net, giving particulars of the principal central stations of the United Kingdom. The tables have been revised to the latest possible date consistent with the exigencies of printing.

CORRESPONDENCE.

[We are not responsible for opinions expressed by Correspondents.]

Mr. Carr's Institution Paper.—The Heat Balance.

SIR,—In reply to the discussion on my paper on the "Selection, Design, and Construction of New Carbonizing Plant at Stretford," at the annual meeting of the Institution of Gas Engineers, I stated that I would communicate the figures of the heat balance on six days' experimental run of the plant, which shows an efficiency of carbonization of 82·04 p.ct. These figures are as follows:

Total heat units in raw coal.
1,538,783 lbs. Dry coal at 13,761·7 B.Th.U. per lb.
Total heat in therms = 211,762 = 100 p.ct.

	Therms.	P.Ct.
COKE—		
Potential heat in surplus coke (dry), 907,230 lbs. at 12,202 B.Th.U. per lb.	110,700	52·27
GAS—		
Therms per ton, 75·96 (corrected) potential heat in gas	53,962	25·48
TAR—		
Estimated yield, 76 lbs. per ton. Dry tar at 14,425 B.Th.U. per lb. Therms in tar	7,788	3·70
STEAM—		
Estimated heat recovered as steam from waste-heat boiler. Waste gases at 538° C. inlet temperature (estimated 60 p.ct. efficiency)	1,249	0·59
Total efficiency of carbonization	..	82·04

The figures relating to the heat value in the tar and steam from the waste-heat boiler are estimated. Observations taken over three months show that the yield of tar is approximately 82 lbs. per ton. In the above estimate, however, the yield has been taken at 76 lbs. per ton, as this was the average yield obtained with similar slack coals over a period of 12 months, but with the old horizontal settings equipped with ascension pipes and hydraulic mains.

In estimating the heat recovery by a waste-heat boiler, the efficiency of the boiler has been taken at 60 p.ct., although a much higher efficiency is guaranteed by the makers. It was considered desirable, however, that this should be taken on the low side, as the boiler was not in operation.

The high heating efficiency of the settings is attributable to the double regenerator, in which the regenerators on either side of the waste-gas flues are used for preheating the secondary air when the setting is working on its own self-contained producer.

Another point raised during the discussion was the speed of the coke telpher machine. The operating speeds are as follows:

Hoisting, full load . . . . . 75 ft. per minute
Travelling, full load . . . . . 600 ft. ,, ,,

The no-load and lowering speeds are in excess of the above speeds.

Gas-Works, Stretford, W. M. CARR.
June 17, 1925.

Sir Dugald Clerk's Institution Paper.

SIR,—Having read with great interest the paper given by Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., M.Inst.C.E., at the Institution meeting, I am sure he will not mind my drawing his attention to the fact that gas for power purposes is not being sold in Sheffield for 6·4d. per therm, as he quotes; but the following prices are in operation, and have been so for about twelve months:

For gas supplied up to:

500 therms	7d. per therm
Over 500 up to 2,500	5½d. ,, ,,
,, 2,500 ,, 15,000	5¼d. ,, ,,
,, 15,000 ,, 30,000	5d. ,, ,,
,, 30,000 therms	4d. ,, ,,

From the above figures it will be seen that gas is sold at 4d. per therm in Sheffield, and a large number of the power users obtain it at that price.

Sheffield Gas Company, R. HALKETT,
June 18, 1925. General Manager and Secretary.

REGISTER OF PATENTS.

Manufacture of Sulphate.—No. 231,788.

GILL, H. A., of Chancery Lane, W.C. 2. A communication from Sté. des Fours à Coke Semet Solvay et Piette.

No. 31,230; Dec. 30, 1924.

The object of this invention is to provide a process of manufacture of sulphate of ammonia giving a perfectly dry and neutral salt, and possessing any acid character due to the presence of acid brine.

The invention is essentially characterized by the fact that, after draining, the salt produced in the saturator is washed with successive solutions of sulphate of ammonia more and more pure; the filtrate after each washing being recovered and used as the less pure washing solution, and the excess of this latter containing the largest amount of acid liquor being conducted into the saturator. The washing solution, composed of neutral sulphate of ammonia, may be alkaline, and for this purpose contain ammonia, ammonium carbonate or ammonium bicarbonate.

Blending and Briquetting for Vertical Retort Operation.—No. 233,508.

WOODALL-DUCKHAM (1920), LTD., and DUCKHAM, A. M'D., both of Grosvenor Gardens, S.W. 1.

No. 10,313; April 25, 1924.

By this invention a continuously operated externally heated vertical retort for carbonizing coal in a single stage at high temperatures, commonly used in the gas-works, is worked by charging it with fuel which has been prepared by blending and briquetting so as to produce a material of uniform chemical and physical characteristics; the patentees claiming that such preparation of the material for a continuous vertical retort under gas-works conditions is in itself a new operation, and obviates difficulties which arise in connection with the working of such retorts.

The following advantages are enumerated: Softening and swelling practically eliminated; high-volatile non-caking coals permissible; ready evolution of volatiles; uniform discharge; minimization of carbon deposit owing to free passage of gases; heat penetration improved; less breeze formed; better steaming conditions; and cyclic use of the pitch made—for binding the briquettes.

Coin-Freed Mechanism.—No. 233,539.

SMITH, E. W., and SMITH METERS, LTD., both of Kennington Park Road, S.E. 11.

No. 13,515; June 2, 1924.

This invention is for a modification of patent No. 219,252, abstracted in the "JOURNAL" for Sept. 3, 1924, p. 754.

The present specification provides that the coin table or lever has an upstanding arm the end of which is fashioned as a tooth or dog adapted to engage a toothed or notched quantity wheel; and a spring is placed in such position—say, coiled round the pivot of the coin table—that it tends to keep the tooth out of engagement with the wheel. This arm is positioned between the pivot and the coin position. The table may be flat, and on it is mounted a slidable block or distance piece adapted to be held by a screw at any required part of a groove formed in the table. This screw may be used alone, in which case it will be slackened and tightened to allow for the movement of and for the fixing of the block, or it may be used with or substituted by a spring washer or equivalent device, which will afford sufficient grip on the block to hold it at any point.

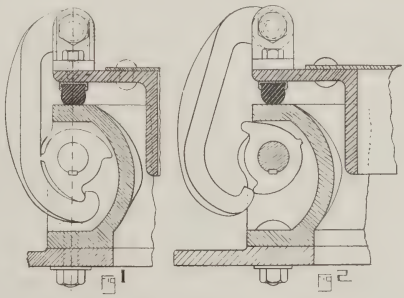
Purifier Lids.—No. 233,400.

CLAPHAM, T. A., and CLARE, R. J. W., both of Keighley.

No. 2819; Feb. 4, 1924.

This invention is for a means of securing the lids of gas purifiers of the well-known type.

Use is made of hooked links pivoted to the cover or lid of the purifier, or to brackets fixed thereon, and rotatable shafts with radial or cam-like projections; the shafts having bearings in the wall of the purifier or in the brackets, in such manner that the cams effect the operation of the links to bring the hooked extremities thereof beyond the plane in which lie the pivots of the links and the shafts. The shafts may each have a second radial projection against which the body of the link abuts when the lid is locked in position; this acting as a stop.



Locking Purifier Covers—Clapham and Clare.

A further "releasing" projection is provided on each of the rotatable shafts, this being so situated that, on the rotation of the shaft to unlock the hooked link, it advances into contact with the link and forces it outwardly to prevent its catching or partially locking itself.

The invention will be clearly understood from the drawings which we reproduce.

Coin-Freed Gas Meters.—No. 233,871.

METROPOLITAN GAS METERS, LTD., and FORSTER, J. D., both of Nottingham.

No. 10,777; May 1, 1924.

This invention relates to coin-freed meters of the kind in which a coin is supported at one portion of its periphery in a slot in a tumbler disc, and bears at the opposite portion against another disc in axial alignment with the former and between adjacent members

of a ring of teeth on the second disc, which is thus locked by the coin to the tumbler disc and will be rotated to adjust the meter mechanism. The tumbler disc is provided with a guide, or box, which directs a coin between two adjacent teeth on the toothed disc.

According to the present invention the box or guide is of a U or trough shape, having at one part a slot, so that it embraces the toothed ring in all positions to which it may be moved. This U-shaped guide is connected to the tumbler disc by means of inclined or diverging extensions secured on either side of the coin. The inner end of the guide so formed may be closed, thus providing a kind of pocket.

Thus, a coin proper to the apparatus will engage the slit in the tumbler disc and the teeth in the toothed disc, and the rotation of the former will ensure the rotation of the latter. A coin too small for the apparatus will merely enter the pocket without engaging the teeth. Also, the toothed ring is inaccessible for fraudulent manipulation.

Geysers.—No. 234,007.

Ewart, J. W., of Crouch End, N. 8.

No. 30,999; Dec. 24, 1924.

According to this invention, the water tray surrounding the vent pipe of a geyser is made integral therewith, and its outer edge or lip over which the water flows is detachably fitted to the upper edge of the cylinder forming the water jacket, and the top of the outer cylinder of the annular chamber is detachably fitted to the upper edge of the said cylinder. This construction of the tray and the top of the outer cylinder allows of their ready removal, and at the same time provides tight joints between them and the parts carrying them.

The horizontal passages through which the water flows from the water jacket into the annular chamber, instead of being arranged at the lower end of the said chamber, are now arranged at the upper end, to allow access thereto when the tray and the top of the outer cylinder are removed.

The condensation gutter is now made independent of the heater casing, and above or below the burner; being thus capable of easy removal.

Gas Ovens.—No. 234,292.

Glover, T., and Wayte, W. H., both of Norwich.

No. 14,266; June 12, 1924.

The invention, for gas ovens, comprises the employment within an outer casing of an oven chamber which is open at its lower end and closed at its upper end, and which is separated from the outer case by air spaces, one or more of which is or are used as a passage or passages along which hot gases can flow from the oven chamber to the outlet in the case.

The oven chamber is a separate unit which can conveniently be inserted within and removed from the outer case, so that the arrangement is particularly useful for the conversion of existing ovens.

After giving details of the construction, referring to diagrams, the patentees point out that the relative disposition of the parts is such that a space is left between the vertical sides, back, and top of the oven chamber and casing, and access is afforded to such spaces for the hot gases by perforations or gaps in the lower flanges of the oven chamber. Hot gases from the burners rise into the interior of the oven chamber, and circulate therefrom to the lower ends of the side or back spaces or both, up which they flow to the flue outlet near the top of the casing. While this is preferred, if desired the gases may escape at the lower end of the casing into the outer atmosphere, the spaces between the oven chamber and casing being then used to provide an air jacket for thermally insulating the oven chamber.

Locking Plug Taps.—No. 234,367.

Main, R. & A., Ltd., of Edmonton, N. 18, and Richardson, A. H., of Winchmore Hill, N. 21.

No. 25,262; Oct. 23, 1924.

This invention relates to a safety device for preventing unintentional turning of a gas plug-tap. The invention provides for a hinged flap suspended from a collar which embraces the supply pipe near the tap; and the catch piece is of such construction and comes into contact with the finger-piece of the tap in such position as to prevent the catch being thrown off when heavy pressure is applied to turn the tap.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.

Progress of Bills.

South Metropolitan Gas Bill: Read a second time, and committed.

Gas Light and Coke Company Bill: Read the third time, with the amendments, and passed; returned to the Commons.

Mansfield Corporation Bill; Read the third time, and passed; sent to the Commons.

Kilmarnock Gas and Water Provisional Order Bill: Read the third time, and passed.

A petition has been deposited on behalf of the London County Council against the South Metropolitan Gas Bill.

Gas Regulation Act.

Copies were presented of drafts of Special Orders proposed to be made by the Board of Trade under section 10 of the Act on the applications of the Colchester Gas Company and the Northampton Gas-light Company.

The draft Special Orders relating to the Trowbridge undertaking of the British Gas Light Company and the Haverfordwest Corporation were approved on the motion of the Earl of Clarendon on behalf of Viscount Peel.

HOUSE OF COMMONS.

Progress of Bills.

Blackpool Improvement, Oldham Corporation, and the Uckfield Gas and Electricity Bills: Read a second time, and committed.

Mansfield Corporation Bill: Read the first time, and referred to the Examiners.

On behalf of the Gas Light and Coke Company, a petition has been presented against the West Ham Corporation Bill.

MISCELLANEOUS NEWS.

ASSOCIATION OF STATUTORY INSPECTORS OF GAS METERS.

Annual General Meeting.

In the New County Hall, Westminster Bridge, S.W., on Wednesday, June 10, the annual general meeting was held of the Association of Statutory Inspectors of Gas Meters. Mr. H. N. Barrow, J.P. (Chairman of the Manchester Justices' Gas Meter Testing Committee), who is President of the Association, was in the chair.

By permission of the London County Council, and with the assistance of Mr. J. Ollis (a Vice-President of the Association), the afternoon was devoted to a visit to the Finsbury gas meter testing office. This testing office is one of the last to be installed, and the visit consequently proved both interesting and instructive.

The President, at the opening of the business proceedings in the morning, expressed his pleasure at seeing present so many representatives of authorities administering the Gas Measures Acts. The more the administrative authorities co-opted with the members of the Association, the better it would be for all of them. The authorities were most anxious to do their duty; and when there was co-operation with inspectors, who were now so well trained, and in every way thoroughly qualified for their work, the lay mind could get guidance from them in the carrying out of this duty. The Executive had held two meetings during the past year—one at Oldham and the other at Manchester; and he could assure them that the Association was going on in every way satisfactorily. Naturally, no great increase in the number of members was to be anticipated; but things were going along steadily.

The Hon. Secretary (Mr. W. Templeton, who is Chief Inspector at the City of Leeds gas meter testing station) read the minutes of the last meeting, and they were confirmed.

Consideration was then given to the annual report of the Council; the paragraphs being discussed *seriatim*.

Mr. George Hume (City of London), the Chairman of the Council, remarked that the regulations were working very well, and few controversial matters had cropped up during the year. The first paragraph of the report, which was in the following terms, did not require any explanation from him.

Meters with Novel or Unusual Features.

With regard to the question of receiving for examination and testing meters containing new or novel features, the Council were instructed at the last annual general meeting to communicate with the Board of Trade, with a view to the introduction of a statutory regulation dealing with this subject. The Council have considered this matter from various points of view; and there appears to be some difficulty in exactly defining new or novel features, and also in drafting a regulation in such form as properly to cover the matter and to assure uniformity of practice, and yet be sufficiently elastic to retain that individual discretion at present exercised by inspectors. The Council wish to have the considered opinion of the members before committing themselves further with the Board of Trade.

Mr. F. Coe (Nottingham) said he felt that, the Council having raised this question, the meeting should register its opinion that the opening of meters was not necessarily involved in this matter. No suggestion was made as to an alteration in the method of testing. These matters should be pointed out to the Board of Trade, in continuation of the correspondence that had been placed before the members. If then the Board did not see their way to make a regulation in accordance with their request, the Association would feel that they

had done what they could. He moved that they communicate with the Board of Trade to this effect.

Mr. H. WEBSTER (Brighton) saw no necessity for taking any further action in the matter.

Mr. W. KENYON (Sheffield) expressed the opinion that this question was very much bigger than it appeared at the moment to the members to be. He moved that a small deputation be appointed to confer with the Board of Trade, before the Association came to a final decision. The deputation, he suggested, should consist of the Chairman of the Council, the Vice-Chairman (Mr. S. B. Langlands), and the Hon. Secretary.

Mr. COE expressed his willingness to withdraw his own proposal in favour of this, if it better met the wishes of the meeting.

Mr. HUME said it was fairly obvious that the Board of Trade were not anxious to take up this matter and shoulder the responsibility In the meter that had raised the point it was not a question of measuring, but of prepayment attachment. If the members were seeking to become responsible for interfering with the automatic attachment, they would be taking on a very big thing. ["Hear, hear."] He thought it would be much better for them to remain where they were, and take no further action. The Board did not, he was sure, wish them to be responsible for the prepayment device. It was the opinion of the majority of the Council that they should take no further steps in the matter.

METERS FOR HOTEL BEDROOMS.

Mr. W. GORDON (Edinburgh), continuing the discussion of this paragraph, said that meters were now being supplied for hotel bedrooms, and similar situations; and they, as inspectors, were interested in the official badge being put on these meters. If they assented to the proposition that check meters need not have an official stamp, they would be doing wrong in the consumers' interests.

Mr. COE replied that his only idea was to let the Board know that the opening of meters was not involved in the Association's suggestion, and that they had in view no different method of testing from that which already existed.

After the resolution that a small deputation should wait upon the Board of Trade had been put to the meeting and negatived,

Mr. HUME remarked that Mr. Gordon's point was quite apart from the matter that had been under discussion. That gentleman raised the question as to whether hotel bedroom meters should come within the regulations of the Sales of Gas Act. So far as he himself was concerned, he believed that there was a difference of opinion on the matter.

Mr. S. B. LANGLANDS (Glasgow) said he thought the Act was fairly clear on the point. Section 13 of the Gas Regulation Act, 1920, was in the following terms:

> All meters by means of which gas is supplied by any undertakers to any consumer shall be stamped in accordance with regulations made by the Board of Trade under their powers in that behalf; and if any undertakers supply gas by means of any meter which is not so stamped, they shall be liable on summary conviction to a fine not exceeding ten pounds.

He held that the hotel proprietor became the "undertaker;" the person who used the measuring instrument was the undertaker.

FEES FOR TESTING HIGH-PRESSURE METERS.

The question was submitted to the Council as to what was the correct charge for examining and testing high-pressure meters. The Council drew attention to the fact that all high-pressure meters must be of a pattern certified by the Board of Trade before they shall be stamped; and the scale of fees should be in accordance with section 24, Gas Meter Regulations, 1920.

Mr. HUME remarked that they had no recognized way of charging. His own method was to charge double what he did for other meters; but this was entirely on his own initiative. The meter makers had not complained; but he would be glad of some ruling on the point.

Mr. F. COLBURN (Birmingham) said his charges were based on the capacity per hour, *plus* a testing fee of 3s. 6d. for the high-pressure index.

Mr. HUME pointed out that the Council thought the best method would be to include any additional charge that might be fixed upon in the supplementary memorandum which was issued by the Board of Trade.

Mr. F. A. ROLFE (London County Council) said it was not legal to charge anything beyond the ordinary testing fee; and something should be done to remedy this defect. The expenditure of an additional amount of time was involved; and the position was a most unsatisfactory one.

It was resolved that the Board of Trade be asked to include in their supplementary memorandum a charge for testing high-pressure meters.

REGULATIONS.

A memorandum was submitted to the Council requesting their interpretation of certain of the regulations. The question raised was as to whether a "Standard" meter should be regarded as a normal meter or as "unduly highly rated." After considerable discussion, it was decided to obtain statistics with regard to the testing of "Standard" meters from various offices; and the result of these figures confirmed the opinion of the majority of the Council. They recommend that "Standard" meters may be regarded as normal meters, and need not be considered as "unduly highly rated."

Mr. HUME said that with new "Standard" meters they had come to the conclusion that it was not necessary to have a double test. The report was that it was a very satisfactory meter. Of course, in the near future conditions might be so altered as to necessitate the amendment of this conclusion.

Mr. E. M. FOSTER (Exeter) thought they ought to have a rule, perhaps based upon the number of revolutions per hour. The meter should not be allowed more than a certain number of revolutions per hour without being marked "unduly highly rated."

Mr. COLBURN stated that, generally, there would not be 1 p.ct. of the new "Standard" meters rejected on the slow-speed test.

Mr. LANGLANDS said it was not the new "Standard" meters which came in for testing that weighed with him, but those which had been in use on the district.

Mr. S. WINTERBOTTOM (Manchester) told the meeting that out of 20,000 odd meters, his rejections were less than 1 p.ct.

Mr. G. W. KAY (Oldham) said he believed he tested a gross, and so little difference was found between the two tests of high rate and low rate that it was thought not to be worth while to go any further. He did not believe they rejected more than 1 out of the gross; and the time taken over two tests was not therefore justified.

Mr. F. W. DALTON (Liverpool) said that, with regard to testing meters at a lower rate than capacity, he so treated all dry meters—new, repaired, and old. They were tested at capacity, and also at one-sixth of their capacity; and it was found that the percentage of rejections of new "Standard" meters was very low. In the case of repaired meters, however, the percentage was much higher. In his office they tested about 36,000 meters a year, of which 20,000 were dry meters. It was found that the percentage of rejections of new and repaired meters was well over 5 p.ct. If, when new, a meter was tested at capacity and also at a lower rate, the chances of it being wrong when it came back after a few years were very much less than would be the case if in the first instance it had been tested only at capacity. A meter should register accurately when it was working at any rate within reason.

Mr. HUME added that in his own case disputed meters that came in from the district were generally put through two tests.

Mr. GORDON thought that, if they continued to have two tests at their own discretion, the valves might be set with greater care than if it became known to the makers that the meter was going to be tested only at full capacity. Therefore they should retain their discretion in the matter of testing.

This clause was agreed to.

10 C.FT. CIRCLE.

The Council were requested to consider whether it was desirable to approach the various interests concerned with regard to the introduction of a 10 c.ft. circle in all new dry meters, as a means of preventing meters with wrong dial plates, &c., getting stamped, which might possibly pass undetected in the ordinary way. The Council are decidedly of opinion that it is not desirable to re-open the question of the testing of indices, and a majority of the Council consider that the benefits to be derived from the introduction of the 10 c.ft. circle do not justify the demand for the compulsory adoption of this innovation.

Mr. DALTON pointed out that quite a number of meters had this 10 c.ft. circle, and that it was a great advantage to inspectors, who had a far better chance of seeing whether the meter index itself was registering properly.

Mr. COE suggested that, by the bringing forward of this matter, meter makers might be influenced to adopt the 10 c.ft. circle as stocks were replenished.

The clause was agreed to, as also was the following:

PUBLICITY.

A proposal was made that the Council should consider the desirability of circulating any item of general interest relating to gas meters and gas-meter testing that appears in the Technical and Daily Press. The Council, however, are of the opinion that the Technical Press is a sufficient medium for the needs, and that the purpose served by circulating news items would not justify the expenditure involved.

OFFICE BEARERS.

The HON. TREASURER (Mr. J. L. Barry) reported a satisfactory financial statement; the balance in hand being over £15.

The following office bearers and Council were next elected or re-elected:

President.—Mr. H. N. Barrow (Manchester)

Vice-Presidents.—Mrs. Councillor Shutte (Salford), Mr. J. Ollis (London), Bailie G. Gott (Glasgow), Bailie Buchanan (Edinburgh), Mr. C. Chambers (Birmingham), Mr. E. J. Gibbon Newcastle-on-Tyne), Alderman Vokes (Southampton), Councillor F. Unwin (Sheffield), Alderman P. R. Gayton (Exeter), and Mr. S. Dyson (Manchester).

Executive Council.—Mr. G. Hume (London), Mr. W. Kenyon (Sheffield), Mr. G. W. Kay (Oldham), Mr. F. Coe (Nottingham), Mr. S. Winterbottom (Manchester), Mr. S. B. Langlands (Glasgow), and Mr. W. Gordon (Edinburgh).

Hon. Secretary.—Mr. W. Templeton.

Hon. Treasurer.—Mr. J. L. Barry.

MR. OLLIS'S RETIREMENT.

The PRESIDENT said that in a very short time they would be deprived of the valuable help of one who had taken a great interest in the Association. He referred to Mr. J. Ollis, of the London County Council, who would soon be retiring. They all knew how greatly he had endeared himself to the members.

Mr. HUME proposed:

> "That this Association desire to convey to their Vice-President, Mr. James Ollis, Chief Officer, Public Control Department, London County Council, their best wishes on the occasion of his retirement from his office with the London County Council, and to express their appreciation of his assistance to the Association and unfailing kindness at all times."

Having been associated with Mr. Ollis for 28 years, he considered it a great privilege to move this resolution. They were much indebted to him for his help in framing the regulations which were in operation to-day.

Mr. LANGLANDS seconded the motion, and expressed his own high appreciation of Mr. Ollis's work.

Mr. CHAMBERS, on behalf of the administrative authorities, supported the resolution, which was unanimously passed.

The London County Council were thanked for the loan of the meeting room; and it was decided that next year's meeting should take place in Glasgow.

GAS REGULATION ACT APPLICATIONS.

The following notices have appeared in the "London Gazette" regarding applications to the Board of Trade under the Act.

SPECIAL ORDERS

Bideford Gas and Coke Company, Ltd.

To enable the Company to raise further capital, to make further provisions as to dividend and as to the supply of gas, and for other purposes.

Ilkeston Corporation.

To authorize the Corporation to supply gas in the parishes of Kirk Hallam and Shipley, to charge for gas on the thermal basis, to borrow money, and to make further provisions with regard to the supply of gas.

Ludlow Union Gas Company, Ltd.

To empower the Company to maintain and continue gas-works, to manufacture and supply gas, to raise additional capital, and for other purposes.

DECLARATION OF CALORIFIC POWER.

Sutton Gas Company.—500 B.Th.U., in substitution for 480 B.Th.U. (Oct. 1.)

Stretford and District Gas Board.—500 B.Th.U. (July 1.)

BIRMINGHAM GAS DEPARTMENT.

Question of Increased Charges.

The Birmingham City Council, at their meeting last week, debated the proposal of the Gas Committee that, as from the June readings of the meters, the price of gas be increased from 2s. 10d. to 3s. 2d. per 1000 c.ft.

Alderman J. H. LLOYD (the Chairman of the Gas Committee), who presented the report, pointed out that the Corporation had to look forward to a continuation during the present year of poor markets, not only for tar and ammonia, but also for coke, and were compelled, as were many other gas undertakings, to increase their prices to meet actual and prospective losses. Even with the increase proposed, their prices, notwithstanding their distance from the pits from which gas coal was obtained, compared very favourably with other undertakings in the country. Though at the moment there was little prospect of an alteration in the residual markets in their favour, the price of gas would be reviewed as soon as circumstances permitted. He complained of the action of the Finance Committee in calling upon the Department to make a contribution to the relief of the rates. This was done by drawing from reserves.

Alderman LANCASTER moved as an amendment that the following be added to the resolution:

> And the Gas Committee be instructed to inquire and report to the Council at an early date on the following matters: (1) The excessive staff and overhead charges of the Department. (2) What gas is being supplied to consumers at under cost price, and why. (3) Why a manufacturer using 1,000,000 c.ft. for power should be charged 5d. per 1000 c.ft. more than one using 5,000,000 c.ft. (4) Why should gas used for lighting be charged 4d. per 1000 c.ft. more than an equal quantity used for power. (5) What expenditure of a capital nature during the last few years has been charged to revenue.

He criticized the general scale of gas charges, and urged that no gas ought to be supplied by the Corporation to any consumer at less (to say the least) than its net cost price, because if this were done it meant that the other consumers had to pay more than they ought in order to balance the loss. The Gas Department for years had been using revenue for what should have been capital expenditure; and as a result the consumers of gas had to pay more than they should be paying.

Mr. THACKER, who is a master gasfitter, supported the amendment. He served his apprenticeship with the Gas Department, and knew there were many ways in which economies could be effected. He wondered, for instance, why gas fires and cookers were fixed free of charge. There were other services rendered free. For clearing the house pipes a charge of 2s. 6d. was made for work that must cost on an average about 10s. to 12s., and in some cases as much as £2.

Alderman LLOYD, in reply, said the Gas Department in the past fifty years had benefited the city to the extent of £2,000,000. Birmingham was not the only place where they had had a bad time. No gas was being sold below cost except for public lighting, and thereby the Gas Department saved the city £24,000 a year—a penny rate.

The amendment was carried.

THE DEPARTMENT'S JUBILEE.

Alderman LLOYD, in moving the adoption of the report as amended, said one gratifying feature of the accounts was the increase in the consumption of gas of 5·35 p.ct. During the year 810,000 tons of coal had been carbonized, as compared with 799,000 tons in the previous year; and 1,735,000 gallons of gas oil had been used in the manufacture of carburetted water gas, as compared with 2,133,000 gallons. The total quantity of gas sold was 12,659 million c.ft., and was a record. The remarkable demand for apparatus of all kinds, both for domestic and industrial use, still continued, and indicated that, unless the unfortunate necessity for increasing the price had a deterrent effect, there was likely to be an even greater consumption of gas during the ensuing year. This was the fiftieth anniversary of the acquisition of the gas undertaking by the Corporation, and undoubtedly the City Council must be gratified with the size and importance it had assumed, and the ever-increasing service it was rendering to the community. Theirs was the largest provincial gas undertaking in the United Kingdom. In all probability a recommendation would be submitted at a future meeting of the Council for an application to be made to the Board of Trade for an Order involving a charge for gas by the therm.

The report as amended was approved.

MALTA AND MEDITERRANEAN GAS COMPANY, LTD.

A Satisfactory Statement.

The Ordinary General Meeting of the Company was held on Tuesday of last week, at the London Offices, Nos. 59 and 60, Gracechurch Street, E.C.—Mr. A. M. PADDON (the Chairman) presiding.

The SECRETARY (Mr. C. J. Daun) read the notice convening the meeting and the Auditors' certificate; and the Directors' report and the statement of accounts were taken as read.

The CHAIRMAN, in moving the adoption of the report and accounts, said the shareholders would have seen that there was nothing but what was of a strictly formal character in the report itself. All matters of ancillary concern were in the accounts, and a remarkable feature of these accounts subsisted in their very close resemblance to those of twelve months ago. In certain respects they were more favourable, because a year ago the figures were based upon a price of gas as between 8s. 6d. and 7s. 10d. per 1000 c.ft., whereas to-day the results were built up on charges ranging from 7s. 10d. to 7s. 6d. per 1000 c.ft.—in other words, a difference of 1s. per 1000 c.ft. This, of course, must have its immediate effect upon the amount received for gas; and this figure had decreased—as he said, necessarily—by £1858. Now, the amount of gas sold, within a small fraction, was exactly the same as that sold twelve months ago; but, notwithstanding this, there had been a gain under the head of receipts from residuals of £400 odd out of the depleted amount he had mentioned; and from fittings, meters, and other subordinate charges another £400 had been accreted. So that the falling off of £1800 was reduced by these additions to something approximating £1000. One of the most gratifying features of the present statement was that the unaccounted-for gas had been reduced by nearly 3 p.ct. One of the proprietors had made complaint of this twelve months ago; and an assurance was then given him that the matter was receiving the attention of the Board and officers. This process was being continued, so that at the present moment the unaccounted-for gas, notwithstanding exceptional disabilities at Malta, was not much higher than would be the case in this country with an undertaking of similar size. As a matter of fact, the figure was down to under 10 p.ct.; and considering the scattered nature of the district, and the way in which the supply per mile of main had been reduced by the very keen electrical competition to which the Company were subjected, he did not think the proprietors could look for the percentage to be very much less than the figure which had now been attained, though endeavours would be unremitting to reduce it still further. Of course, a very much better criterion of the real nature of the working than this was the amount of gas sold per ton of coal carbonized. The percentage of unaccounted-for gas must in a sense be an estimated figure; but when they took the sale of gas per ton, they got to something absolutely final, and this stood at a highly creditable figure in the accounts. On the debit side of the statement, coal had cost them £1574 less, and manufacturing charges had been reduced by nearly £100; but they had expended a little more lavishly upon maintenance of works, which was increased by some £1600. There had been a reduction of over £300 in the appropriation for corporation profits tax, which now figured at £110. He thought this was rather a matter of technical accountancy, because it should have disappeared, and would inevitably disappear from the next account. Turning to the general balance-sheet, it would be seen that the amount available was adequate to meet all their requirements.

A SOUND FINANCIAL POSITION.

On the credit side, investments (which covered the amortizement account, the reserve account, and the general investment account) had been split-up and appropriated to their particular purposes. Thus it was a very different statement from what would be the case were the investments simply aggregated. Whereas the book value of these investments was £56,000, the actual value at the date of the accounts was £61,364—nearly £7000 more than a year ago. If they would compare this £61,000 odd with the debit statement on the opposite side, which showed the total capital liabilities to be £123,000, they would realize how very sound the financial position of the Company was becoming, because it was tantamount to saying that one-half of the capital had been written off. The amortizement account was increased by £1607, and the reserve account (by interest and by the appropriation mentioned in the report) was increased by £4485. After this procedure had been carried out, and allowance had been made for the interim dividend, the amount standing at credit of profit and loss account was £13,704, which was £506 more than a year ago. This was the final figure of the whole account; and he thought the proprietors would agree with him that it was a very satisfactory statement to be able to present. He had told them at the last meeting that the Board thought the Company could get an increase in their business. Everything at that time pointed in this direction; and it was not the fault of the business that it had not so increased. Just, however, as they had got fairly into the middle of the account, the Egyptians started one of their political movements, and the Fleet had to go to there with a considerable proportion of the garrison. When the Fleet moved away from Malta, it meant that 30,000 people left the Company's area of supply; and considering the size of the undertaking, this was a very disturbing factor. But all they could do was to wait for them to come back again, and they had come back. As a result, so far during the current financial year the increase in the Company's business had been something like 10 p.ct.; and he did not see why this state of affairs should not continue, because their Engineer and General Manager had reported that, for the first time for many years—not only since the war, but before it—building activities were manifesting themselves in Malta. Therefore the Engineer considered that the prospects of the undertaking were distinctly more favourable than he had hitherto known them to be. They had not much to fear from electrical competition, because they had had it for the last thirty years; and in Malta (which was essentially a Government settlement) the production and sale of electricity were in the hands of the Government. Therefore there was not much to suffer from electrical competition beyond what they had already suffered. In this country there was evidence of some disturbance in the minds of gas investors with regard to the Govern-

ment and electricity; but he thought it did not bode particularly well for an industry when the Government took a hand in it. He did not believe that those who formed the fanciful ideas of which one now heard would translate their expectations into tangible results.

Mr. A. W. OKE seconded the motion, which was carried unanimously without discussion.

The CHAIRMAN next moved: "That a dividend of 3¼ p.ct. (making, with the interim dividend paid in December last, 6 p.ct. for the year), free of income-tax, be declared on the ordinary shares, and dividends of 3½ p.ct. and 3¾ p.ct., less income-tax, be declared on the first and second preference shares respectively."

Mr. STRACHAN C. CLARKE seconded the proposition, which was agreed to.

The retiring Director (Mr. E. L. Burton, F.S.A.A.) was re-elected, on the proposition of the CHAIRMAN, seconded by Mr. F. R. SMITH; and the Auditors (Messrs. William Cash, F.C.A., and Mr. Hyde C. Burton, A.C.A.) were similarly reappointed, on the motion of Mr. SMITH, seconded by Mr. F. W. CHURCH.

Mr. W. H. DODGSON said he was assured of the support of all the proprietors in proposing a hearty vote of thanks to the Chairman, Directors, and officers of the Company for their services during the past year. The results recorded were most excellent; and he was glad to hear that the Company's prospects were still favourable.

Mr. CHURCH seconded the proposition, which was heartily agreed to.

The CHAIRMAN, acknowledging the vote, remarked that the strength of the undertaking really depended upon the excellence of the working results. Personally, with an extensive experience of gas undertakings, he had never known better working results than those which came in month by month from their Malta Station. The efforts of the Board and the officers would be directed towards the maintenance of these results.

GAS DEVELOPMENT AT NANTWICH.

The coming-of-age of the Nantwich gas undertaking as a publicly-owned concern was celebrated by the installation of an important new carbonizing plant, which, on June 17, was inspected by about sixty visitors, who were afterwards entertained to luncheon.

Assembling at the works, the visitors were welcomed by Mr. James Bowyer, Chairman of the Council, and Mr. A. Rollings, Chairman of the Gas and Lighting Committee, who expressed the hope that the inauguration of the latest plant would mark the commencement of a new era of success for the undertaking.

The retort bench consists of four through beds of 24 in. by 16 in. D-section retorts 16 ft. long. The settings are of Gibbons and Masters' latest tube regenerative pattern, with the Sydenham grate. A separate house has been built for a 25-KW. gas-engine driven electrical generator. The plant has an approximate gas-making capacity of 350,000 c.ft. per day.

Luncheon was served at the Brine Baths Hotel, where Mr. James Bowyer presided. He was supported by Mr. A. Rollings (Chairman of the Gas Committee) and Mr. A. Mackay (Chief Gas Engineer for Stoke-on-Trent).

Mr. A. MACKAY proposed the toast of "The Nantwich Urban District Council and the Gas Undertaking," and heartily congratulated the Council upon their progressive step. He complimented Mr. Vernon (the Manager of the works) on the work he had carried through in preparing the scheme, and said the ratepayers should be grateful to the Council for having taken a step which would lead to a cheapening of the gas supply.

Mr. A. ROLLINGS, in response, traced the history of the gas undertaking in Nantwich, and mentioned that the total cost to date, including the new plant and working capital, was £100,600. During the time the ratepayers had been the owners, £35,783 had been paid off, leaving a balance of £64,817; and the prospect for the undertaking was now considerably brighter. He announced that the Gas Committee had decided upon a reduction in the price of gas. Basing his estimate on last year's consumption, he said the total saving to consumers would be about £1700 a year.

Mr. C. S. BENNETT, replying to the tribute paid to the contractors, said he was convinced that the town would reap great benefits from bringing their works up to date. The work could not have been carried through so well but for the co-operation of Mr. Vernon.

TRADE NOTES.

Spencer-Bonecourt Kirke Boilers and Superheaters.

Messrs. Spencer-Bonecourt, Ltd., of London and Hitchin, have brought out an enlarged second edition of their catalogue of the Kirke boiler, which will doubtless be of interest to many readers of the "JOURNAL."

Gas-Works Plant.

The Koppers Coke Oven Company, Ltd., of No. 301, Glossop Road, Sheffield, have published a booklet in which they describe the gas plant which they manufacture. It is an excellent publication, and will prove of value to gas engineers.

The "Mainstay" Cooker.

Messrs. R. & A. Main, Ltd., of London and Falkirk, have published a very interesting booklet entitled "The Story of the Mainstay Cooker." Both the illustrations and the text have been excellently prepared; and the publication as a whole does credit to the firm.

Smoke-Consuming Door.

Messrs. Meldrums, Ltd., of Timperley, have brought out a smoke-consuming door to take the place of the ordinary firing door fitted on vertical and Cochran boilers. It consists of a double-walled door having steam jets over and along a top opening. These jets deliver secondary air down and through the inside of the door just at the point of combustion. The jets need only be in operation for a half to one minute after a fresh charge of fuel.

NORTH-EAST COAST COAL TRADE.

From our Own Correspondent.

Although present indications are pointing to the serious possibility of trouble and stoppages in the coal trade, there is a general feeling of relief that at any rate a crisis is approaching of the present situation, which has become quite hopeless. Pits have, for some considerable time, been closing on all sides, and still the demand is far from adequate to meet the supplies available from those collieries which are struggling on, and it has long been obvious that, except for something quite unexpected turning up, no improvement could be looked for on the basis of present costs.

It is to be hoped that the uncertainty will not last long, and that something definite will speedily be evolved to put an end to the present position, which is intolerable alike to owners and men.

In the meantime, judging from previous experience, there is more than likely to be some stiffening in the demand, though stocks on every hand are reported to be so high that it can hardly be expected to be of much account. This week is the great annual Newcastle Race Week holiday, and the Exchange will be closed half-days each day.

Closing quotations for gas coals were nominally 18s. 9d. f.o.b. for Wear Specials, and 18s. for best qualities. Seconds were 15s. 6d., but at these prices were probably discountable for prompt and definite business. Coking makes were very weak, and best Durham bunkers were obtainable at 16s. 3d.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

Collieries are not inclined to yield to the pressure of those gas engineers who have withheld their contracts till the last moment in the hope of getting yet larger concessions. Business has been done at 3s., and in some cases 3s. 6d., below the old contract rates; lower than this the collieries will not go. There is little change to record in the general market position. Smalls have firmed up to the extent of about 6d. as a consequence of the drastic reduction of output which has been effected. Demand continues to decrease, and values can only be steadied by making a corresponding readjustment of supplies. The expiration of the agreement between the owners and the miners is apathetically awaited. So far as the gas undertakings are concerned they probably never had larger reserves. Stocks in other directions are considerable having regard to the slow rate of consumption.

Industrialists who have accommodation for stacking fuel are generally well insured against contingencies. Those who need to replenish every week or fortnight betray no anxiety as to the continuity of supplies. Nobody believes a national hold-up is imminent. The calmness of the market has been undisturbed throughout the protracted negotiations on the labour question. What most industrialists feel is that, if the cost of coal cannot be stabilized on a substantially lower basis than has prevailed till recently, it does not matter very much what happens: a trade revival is not to be hoped for, and many of the works may as well be closed as kept going in the unprofitable conditions to which they have been reduced.

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

There is a great deal of uncertainty in regard to the future prospects of the coal trade by reason of the fact that present prices do not warrant collieries producing the lower grade fuels continuing operations. What effect this will have on the prices of available supplies remains to be seen. So far, the negotiations between the owners and the miners have not led to any enlightenment.

Gas coals are moving spasmodically with no standardized rates for forward delivery, and contracts are being fixed up at varying rates in accordance with local circumstances. The possibility of a strike may lead to a shortening of the market, but any stoppage will not be of such a prolonged nature as to inconvenience the consumers.

House coals are moving slowly, while industrially there is no improvement in the demand; so that as a result fuels for prompt delivery are available at discounted rates. There is no improvement in the export section. In Lancashire there is a moderate demand for industrial coal. Prices are unchanged; but there is a good deal of outside slack coming in at from 10s. to 12s. per ton. For high-class Lancashire slacks from 15s. to 16s. at the pits is asked.

Hull prices at the week-end were: South Yorkshire.—Hards, Association, 19s. 3d. to 19s. 6d.; screened gas coal, 16s. 6d. to 17s. 6d.; washed trebles, 17s. to 17s. 6d.; washed doubles, 16s. to 16s. 6d.; washed singles, 15s.; washed smalls, 11s.; unwashed doubles, 15s.; rough slack, 10s.; smithy peas, 16s. 6d. to 18s. 6d. West Yorkshire.—Hartleys, 15s. to 17s.; screened gas coal, 16s.; washed trebles, 16s. 6d. to 17s.; washed doubles, 14s. 6d. to 15s.; washed singles, 13s. 6d. to 14s.; washed smalls, 10s. to 11s.; unwashed trebles, 15s.; unwashed doubles, 12s. to 13s.; rough slack, 9s. 6d.; coking smalls, 9s. to 10s. Derbyshire and Notts.—Top hards, 19s. 3d. to 20s.; washed trebles, 17s. to 17s. 6d.; washed doubles, 15s.; washed singles, 14s.; washed smalls, 9s. 6d.; unwashed doubles, 13s. 6d. to 14s. 6d.; rough slack, 9s. 3d. to 9s. 9d. Yorkshire, Derby, and Notts.—Screened steam coal, 15s. to 16s.; gas coke, 19s. to 20s.; furnace coke, 17s. per ton.

James Keith & Blackman.—The Directors in their report state that the amount of business done during the year to March 31 last was greater than that of the previous year. After providing for debenture interest, preference dividend, and making sufficient allowance for depreciation and reserves against doubtful debts, the accounts show an available balance of £31,638. The Directors recommend a dividend on the ordinary shares of 10 p.ct., less tax, and the transfer to reserve of £5000, carrying forward £11,138.

CURRENT SALES OF GAS PRODUCTS.

The London Market for Tar, Tar Products, and Sulphate.

LONDON, *June 22.*

The position of pitch continues unchanged, and the price remains nominal at about 41s. to 42s. per ton.

In the meantime, the demand for road tar continues unabated; most makers being exceedingly busy with orders.

Creosote is steady and unchanged at about 7d. per gallon net, in bulk.

Solvent naphtha is in short supply at about 1s. 8d. per gallon for 95/160 quality.

Pure benzole and pure toluole are firm at 1s. 11d. to 2s. per gallon.

Tar Products in the Provinces.

June 22.

There is little fresh to report concerning the markets for tar products.

In pitch there have been a few inquiries during the past week, but little business is reported.

Creosote appears to be steady.

Benzoles and solvent naphtha are in fair demand.

In crude carbolic one or two sales are reported at low prices.

The average values for gas-works products during last week were: Gas-works coal-tar, 26s. to 31s. Pitch, East Coast, 39s. to 40s. f.o.b. West Coast—Manchester, 34s. to 35s.; Liverpool, 35s. to 36s.; Clyde, 38s. to 39s.; Benzole, 90 p.ct., North, 1s. 7½d. to 1s. 8½d.; crude, 65 p.ct. at 120° C., 1s. to 1s. 1d., naked at makers' works; 50-90 p.ct., naked, North, 1s. 7½d. to 1s. 8½d. Toluole, naked, North, 1s. 6½d. to 1s. 7½d. nominal. Coal-tar crude naphtha, in bulk, North, 7½d. to 8½d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. to 1s. 2d. Creosote, in bulk, North, liquid, 5⅝d. to 6d.; salty, 5⅝d. to 5⅞d.; Scotland, 5½d. to 5⅝d. Heavy oils, in bulk, North, 6½d. to 7d. Carbolic acid, 1s. 5d. to 1s. 6d. prompt. Naphthalene, £11 to £14; salts, £4 to £5, bags included. Anthracene, "A" quality, 2½d. per minimum 40 p.ct., purely nominal; "B" quality unsaleable.

At a meeting of the Council of the Midland Branch of the National Union of Manufacturers at Birmingham last week, concern was expressed at the proposed raising of the price of gas in the city. One local firm wrote that a rise of 3d. to 4d. per 1000 c.ft. would cost them from £300 to £400 per year extra. It was agreed to write to the Lord Mayor calling attention to the fact that the rise might induce certain manufacturers and large consumers to put down their own gas-producing plant, in which case the price would have to be raised to the general public, and asking whether some differentiation in the price could not be made in favour of large consumers and manufacturers.

CONTRACTS OPEN.

Coal.

The Haverhill Urban District Council are inviting tenders for the supply of 1500 tons of best gas coal. [See advert. on p. 1038.]

The Urban District Council of Colwyn Bay and Colwyn are inviting tenders for the supply of coal for gas making purposes. [See advert. on p. 1038.]

The Gas Committee of the Borough of Clitheroe are inviting tenders for the supply of 8000 tons of gas nuts, unscreened coal, and rough dry slack. [See advert. on p. 1038.]

Excavating, Laying, and Reinstating Pipes.

Tenders are invited by the Lancaster Corporation Gas Department for excavating, laying, and reinstating 1500 yards of 18-in. gas-mains. [See advert. on p. 1038.]

Pipes (Steam and Gas).

The Town Council of Middleton are inviting tenders for cast iron socket and spigot pipes and wrought iron steam tubes and fittings. [See advert. on p. 1038.]

Gas Week in Kendal.—The Kendal Corporation Gas and Water Department are to be congratulated on the excellent exhibition which they are holding this week in the Town Hall, Kendal. Opened on Monday last by Alderman J. J. Thomas, J.P. (the Chairman of the Gas and Water Committee), the exhibition is attracting a large number of visitors. Richmond's popular "Bungalow" and "Ranelagh" cookers are conspicuous among a wide selection of cooking, water heating, and heating equipment manufactured by the Richmond Gas Stove and Meter Company, Ltd., and supplied by the Corporation on special cash and hire-purchase terms. No charge is being made for fixing. Cookery lectures and demonstrations are being given each afternoon and evening.

Successful Year at Hinckley.—The Hinckley Gas-Works last year made a net profit of £3092, besides reducing the price of gas by 4d. per 1000 c.ft. "The working results were never better, and constituted a record in every respect," said Mr. F. Burton (the Chairman of the Committee) in presenting the statement of accounts for the year ended March 31. While the cost of coal and wages (which represented 83 p.ct. of the working expenses) was over 100 p.ct. higher than in 1913, the average price charged for gas was only 33 p.ct. more. The gas sold was 164,777,700 c.ft., as compared with 155,270,400 c.ft. in the previous year; while the quantity unaccounted for was only 1·44 p.ct.—the lowest figure on record, except in 1913, when it was 1·4 p.ct. Mr. Bott said that the Council and the town had reason to congratulate themselves when they read of neighbouring towns being faced with an increase in the price of gas. Thanks were due to their Manager (Mr. Fred Lee). The Chairman (Mr. Hurst) commented upon the energy and foresight of the Manager, who was accorded a vote of thanks.

GAS REGULATION ACT, 1920.

ALEXANDER WRIGHT

& CO., LTD.,

1, WESTMINSTER PALACE GARDENS,

WESTMINSTER, S.W. 1.

Gas Exhibition at Denton.

The advantages of cooking by gas were ably demonstrated last week at Denton, where an extremely well-arranged exhibition was held in the Co-Operative Hall, Ashton Road. People who still cling to the use of the coal range for cooking and water heating responded to the Gas Department's invitation in large numbers, while others whose gas equipment is out-of-date or insufficient for growing needs also evinced a gratifying interest. The exhibition was arranged by the Denton Urban District Council Gas Department; and prominent on the stand were Richmond's popular "Bungalow" cookers, as well as Wilsons & Mathiesons' cookers and their famous "Sunbeam" gas grates. A very complete and comprehensive display of apparatus which may be had on special cash or hire-purchase terms was tastefully set-out; and many of the appliances were shown fitted and in operation. Cookery lectures were given each afternoon and evening throughout the period of the exhibition, from June 15 to 19. These lectures and practical demonstrations proved a very popular feature of this "Gas Week" in Denton.

Eastbourne Gas Company's Loan Capital.—We understand that the £50,000 of 5 p.ct. debenture stock in the Eastbourne Gas Company recently advertised in our columns was fully subscribed, and that several of those who tendered at the minimum price of £95 p.ct. failed to obtain a full allotment. We are informed that the average price realized was £96 10s. p.ct.

Barrow Gas Undertaking.—At a meeting of the Barrow Town Council on Monday, June 8, Alderman R. Thompson, Chairman of the Gas and Water Committee, gave the annual statement upon the working of the undertaking, which, he pointed out, had a capital account of three-quarters of a million. There had been an increase in the quantity of gas sold of 19,932,000 c.ft., equal to 7 p.ct.; the total quantity sold being 303,907,000 c.ft. The number of gas cooking stoves in use at the end of the financial year was 101 in excess of the previous year; the total now being 10,324. The report was unanimously approved; and in reply to a question, Alderman Thompson said that gas would be supplied to the residents in Vickerstown, Walney Island, as soon as the necessary arrangements had been completed.

Torquay Gas Company's Carbonizing Plant.—Major R. P. Kitson presided last Wednesday at an extraordinary meeting of the Torquay and Paignton Gas Company, when the Directors sought sanction to create and issue debenture stock to the amount of £53,310. The Chairman explained that the money was primarily required in connection with the erection of vertical retorts in place of the horizontal settings. By reason of the amalgamation of Paignton with Torquay, it had been decided to discontinue the manufacture of gas at the Paignton works, and to instal larger carbonizing plant at the Torquay works. The Company would not only obtain increased results, but the installation of vertical retorts would improve the amenities of the neighbourhood. The progress of the Company continued to give great satisfaction to the Directors; the reports being always of increased consumption. The shareholders sanctioned the Directors' proposals.

Truro Gas Company and Electricity.—The Truro Corporation, who had an electricity scheme of their own under consideration for a long while, and finally rejected it, have had a number of offers from private undertakings to supply the city with electricity. Several of these were placed before the Town Council last week, when it was decided to refer them to the Electric Lighting Committee. One of the offers was from the Truro Gas Company. This was to provide electricity within six months of obtaining the necessary authority, with power to the Corporation to purchase the undertaking, if they desired, after seven years. The price to be charged for lighting purposes would be 10d. per unit, and for power 5d. per unit, with authority to allow discount for large consumption or for current used for special purposes. They stated that the only hope for an economic supply was for it to be generated and distributed by the existing gas undertaking. Mr. E. J. Larch (the Chairman of the Electric Light Committee) said the Gas Company's offer was reasonable, but they should consider whether the general position had altered since 1913, when they fought the Gas Company over the Provisional Order.

The Burnley Gas Engineer (Mr. J. H. Clegg) has been authorized to visit the Continent for the purpose of inspecting in operation a Sulzer plant for the dry cooling of coke.

Blackpool Gas-Works report an increase for the four weeks ended June 17, the output being over 69⅛ million c.ft.—an increase of 4⅜ millions on last year. The increase is equivalent to 7·31 p.ct. During May, 133 new gas consumers were connected.

In connection with the proposed purchase of the local gas undertaking, the Towyn Urban District Council are appointing a gas expert who will make a full report upon the plant, mains, &c., of the Dysynni Gas Company at Towyn and Aberdovey, and prepare a valuation of the plant, machinery, &c.

Presentations followed presentations at a meeting of the members of the Luton Gas Company's First Aid Class on Wednesday last, the distribution of certificates, vouchers, and medallions awarded on the recent examination being followed by gifts of a different kind. Mr. William Phillips (the Secretary and Manager of the Company) presided, and the awards were presented by Mrs. Phillips. All the 21 entrants were successful, 2 receiving first-class certificates, 5 second-year vouchers, and the remaining 14 medallions which signified that they were fully efficient in first-aid work. Mrs. Phillips was also called on to make a presentation of a calendar to Dr. Archibald, in recognition of his services during the past three years. The Class Secretary (Mr. L. Scrivener) and the Instructor (Mr. F. Hucklesby) were given a silver rose bowl and tobacco pouch respectively. The presentation of a cheque for £2 2s. from the Gas Company to the local brigade of the St. John Ambulance Corps was also made.

STOCK MARKET REPORT.

THE Stock Markets last week were uncertain, the conditions of the industrial and financial circles doubtless contributing thereto. The position is not likely to be improved by the new issues announcements of the current week, which totalled to the sum of over £6,000,000, the principal of which is the Union Cold Storage issue of £3,220,000 6 p.ct. preference shares. Prices, especially of gilt-edged stocks, continued to fall, and interest displayed in any one section was speedily dissipated by a volume of sellers.

Home Rails, however, exhibited a distinct change for the better on the more hopeful reports with regard to the labour problems. Great Western, Midland and Scottish, North Eastern, and Southern stocks improved from 3 to 5 points. Industrials, on the other hand, were more varied. Reports from the different centres show that although there is a good deal of disorganization and uncertainty in some industries, others are doing exceptionally well, as for instance the artificial silk industry. Tobaccos were reactionary, and Rubbers slowed-up on profit-taking sales.

There was a normal number of transactions in the Gas Market, and the changes in the quotations were unimportant. The Sheffield three stocks were marked up 1 point; but British ordinary and Liverpool ordinary fell 1 and 1¼ points respectively. It will be noticed that the Bombay £5 shares, which have been split-up into £1 shares, are now quoted in the list at an average of par. This adjustment of the face value will probably bring about an improvement in the market value of the shares, which on an 8 p.ct. dividend are an attractive investment.

The following transactions were recorded during the week.

On Monday, Bombay 5, 5¼, Bournemouth "B" 12$\frac{9}{16}$, 12$\frac{11}{16}$, 3 p.ct. debenture 58$\frac{3}{4}$, Brentford "A" 95, Brighton and Hove "A" 124½, 125, British 110, Commercial 3½ p.ct. 86, Continental Union 7 p.ct. preference 87$\frac{3}{4}$ *ex* div., European 7$\frac{3}{8}$, Gas Light and Coke 83$\frac{1}{2}$, 83$\frac{3}{8}$, 83$\frac{3}{4}$, 84, 84$\frac{1}{4}$, 3$\frac{3}{4}$ p.ct. maximum 62, 62$\frac{1}{2}$d. 4 p.ct. preference 78$\frac{1}{4}$, 78$\frac{3}{4}$, 79, 3 p.ct. debenture 59$\frac{1}{2}$ *ex* div., Imperial Continental 145$\frac{1}{2}$, 146, 147$\frac{1}{2}$, Lea Bridge 98, Malta and Mediterranean 88s. 9d., 91s. 3d., Montevideo 67, 67$\frac{1}{2}$ *ex* div., Plymouth and Stonehouse 111, Primitiva 8s. 9d., 9s., 9s. 3d., 9s. 4½d., South Metropolitan 93½, 93$\frac{7}{8}$, 94, 3 p.ct. debenture 59$\frac{1}{8}$, 61, South Suburban 5 p.ct. 94, 96, 5 p.ct. debenture 98½, Wandsworth (Wimbledon Stock) 105. Supplementary prices, Bath 5 p.ct. debenture 95$\frac{1}{2}$.

On Tuesday, Alliance and Dublin 65, Brentford 5 p.ct. preference 95, Gas Light and Coke 83½, 83$\frac{3}{4}$, 84, 84$\frac{1}{4}$, 3 p.ct. debenture 50$\frac{1}{2}$, 59$\frac{3}{8}$ *ex* div., Imperial Continental 145, 145$\frac{1}{4}$, 145$\frac{3}{4}$, 146$\frac{1}{2}$, Montevideo 67 *ex* div., Portsea Island "C" 97$\frac{1}{2}$, 98, "D" and "E" 80$\frac{1}{2}$, 81, Primitiva 9s., 9s. 6d., South Metropolitan 94$\frac{3}{4}$. Supplementary prices, Sunderland 6 p.ct. maximum 104$\frac{1}{2}$.

On Wednesday, Alliance and Dublin 65, 65$\frac{1}{2}$, Cardiff 104, European 7$\frac{1}{16}$, 7$\frac{1}{8}$, Gas Light and Coke 83½, 83$\frac{3}{4}$, 84. Imperial Continental 145. Montevideo 68 *ex* div., Oriental 104, 104$\frac{1}{2}$, 104$\frac{3}{4}$, Primitiva 9s. 4$\frac{3}{4}$d., 9s. 9d., 9s. 10$\frac{3}{4}$d., 4 p.ct. (River Plate) debenture 66$\frac{1}{4}$, 66$\frac{3}{4}$, South Suburban 5 p.ct. 94, 95, Tottenham 5$\frac{3}{8}$ p.ct. preference 104$\frac{1}{2}$. Supplementary prices, British Norwich 3$\frac{1}{2}$ p.ct. mortgage debentures 63$\frac{1}{2}$.

On Thursday, Continental Union 35, Gas Light and Coke 83$\frac{3}{8}$, 83$\frac{1}{2}$, 83$\frac{5}{8}$, 84, 84$\frac{1}{4}$, 3$\frac{1}{2}$ p.ct. maximum 62, Hastings and St. Leonards 5 p.ct. converted 95, 95$\frac{3}{4}$, Imperial Continental 144, North Middlesex 118, Primitiva 9s. 6d., 9s. 10$\frac{1}{2}$d., 10s., South Metropolitan 93$\frac{1}{2}$, 93$\frac{3}{4}$, 93$\frac{7}{8}$, 6$\frac{1}{2}$ p.ct. debenture 103, 103$\frac{1}{2}$, Swansea 7 p.ct. preference 103$\frac{1}{2}$. Supplementary prices, Barnet "C" 147$\frac{1}{2}$, East Grinstead "A" 12$\frac{3}{4}$, 13, Mid-Kent 54$\frac{3}{4}$.

On Friday, Alliance and Dublin 65, Commercial 86, 86$\frac{1}{2}$, Gas Light and Coke 83$\frac{1}{2}$, 84, 84$\frac{1}{4}$, 4 p.ct. preference 78$\frac{3}{4}$, Montevideo 67$\frac{1}{2}$ *ex* div., Oriental 103, Primitiva 10s., South Metropolitan 93$\frac{1}{2}$, 94, 94$\frac{1}{4}$, 94$\frac{3}{4}$, Tottenham "B" 94, 96. Supplementary prices, Barnet "B" 145.

Financiers are still in doubt about the ultimate effect of the restoration of the Gold Standard. So far, with no increase in the Bank Rate and an increase in the stock of gold, all appears to have gone well. During the past week money was in plentiful supply. Over the week-end the rate for loans was 3$\frac{3}{4}$ p.ct., but old day-to-day loans were renewed at 3½ p.ct. The result of the Treasury Bill allotment showed a rise of nearly 5d., to £4 8s. 3·35d. p.ct.

The feature of the Foreign Exchange Market was the inexplicable slump in the Italian exchange; but assisted by New York buying at the end of the week, the rate recovered slightly, and finally closed at 129 lire. The Paris cheque displayed more firmness and closed at 102.62½, and Belgian francs at 103.90. Sterling on New York rose slightly to 4.86.

The Silver Market was very quiet, and the price for cash—31½d. per oz.—was unaltered. Gold remained firm at 84s. 11½d. per oz.

The Bank Rate is 5 p.ct., to which it was raised from 4 p.ct. on March 5. Bankers' deposit rates are 3 p.ct. The deposit rates of the discount houses are 3 p.ct. at call and 3½ p.ct. at notice.

APPOINTMENTS & PROMOTIONS.

Gas Salesmen, Showroom Attendants, and Manufacturers' Representatives are invited to send information as to promotion or changes in appointment for publication under this heading.

NOTICES.

Copies of this Supplement for Distribution among Members of the Gas Sales Staff, can be obtained at the office of the "Journal." Price per 100, 35s.; 50, 18s.; per doz. 4s. 6d.—plus postage; single copies, 5d. (stamps for single copies with order).

The Supplement is published on the Last Wednesday of each Month.

The Editor reserves to himself the right to delete from, or modify any, communications submitted dealing with matters of a purely personal nature.

All communications should be addressed to

WALTER KING, Ltd.,
"Gas Salesman" Supplement,
11, Bolt Court, Fleet Street,
London, E.C. 4.

Telephone Number: CENTRAL 6055.
Telegrams: "GASKING, FLEET, LONDON."

EDITORIAL.

Cost and Benefits of Maintenance.

The maintenance of consumers' appliances in a high state of efficiency means the maintenance of much else. It results in the promotion of satisfaction, which inures to the maintenance of existing business, of the rate of progress of new business, of the resisting power of the industry to competition, and so forth. The gas salesman is therefore largely concerned in the much-discussed policy of the inspection, regulation, and maintenance of consumers' appliances in the best condition for rendering good service; the consumer only paying directly for the materials used. But though the gas salesman is considerably interested in the matter, the adoption of the policy is one that—and rightly so—can only be brought about by the advice of the chief executive officer, and its acceptance by the administrative body. At the same time it is a subject about which the gas salesman should have cognizance of all the *pros* and *cons*, though the weight of the *pros* leaves the *cons* dangling high in the air in rather a stupid fashion.

Some undertakings have had long experience of the system of inspection, adjustment, and maintenance; but they are relatively few, though there is a steady numerical growth. One thing, however, that is striking about the application of the policy is that there is never any return by those with experience to the old policy of allowing things to take care of themselves the other side of the consumers' meters. Another point is that the objections to the adoption of the policy only come from those who have no experience of its intrinsic merits and business protecting and promoting qualities. We have here a remarkable example of the power of tradition, and of refusal to recognize that times and conditions are mutable, and that methods should change to conform. The gas industry is much stronger than it was (say) a quarter of a century ago. During that period it has broadened and deepened its base in an extraordinary manner; and it sees before it territory for further development of an order which should inspire its men to do everything possible to obtain a large share of it. Into its occupation the electrical competitors are also striving to move; and they appear to be getting, in opposition to national interests, the upper place in political influence. That influence can only be an aid; the determining factor must be public preference. We have therefore to combat the political influence by building-up public preference. That is the gas industry's soundest policy; and it can best be done by ensuring efficiency and economy in the utilization of gas in the homes and industrial establishments of the country.

Recently the North British Association of Gas Managers have been further considering the question of the adoption of the policy of systematic and periodical inspection, adjustment, and maintenance of consumers' appliances; and we urge all gas salesmen to read the valuable contributions to the subject which were made by Mr. J. W. Napier, of Alloa, Mr. George Keillor, of Greenock, and Mr. J. W. M'Lusky, of Glasgow. They will be found in the report of the proceedings at the Spring Meeting of the Association, as reported in the "Gas Journal" [see April 8, 15, and 22]. The authors all speak from experience; and upon their experience they appeal to gas undertakings which have not yet applied the system to do so without delay. Advice founded upon experience is better than opposing argument based upon inexperience. The benefits of the policy are mutual as between consumers and undertakings. The consumers, through the expert attention, become more and more satisfied with the service. The satisfaction is due to the enhanced efficiency and economy that result; and contentment with existing appliances makes easier the road to the extension of the use of gas through the same service-pipe, which is an advantage to the gas salesman and to the undertaking he serves. What on earth is the good of a gas salesman trying to do further business with a discontented consumer, who does not know how to manage his appliances, or, if he does, declines to take the trouble? The benefit of giving good service by supervision up to

the gas consumers' terminals is manifold to the gas undertaking. It protects existing business, it promotes extended custom, the additional custom helps to reduce capital, establishment, manufacturing, and distribution charges to the benefit of both gas consumers and suppliers; complaints are reduced; and competitors find the barriers to making headway considerably strengthened. And mark this: Where there are diseased parts in the system of a trading organization such as gas—of the order found by Mr. M'Lusky in a survey of the indoor conditions in Glasgow—we may be sure that continued neglect will intensify the disease. He profits most who serves best. Those who are discerning, those who have the capacity for determining to-day what is best for the morrow, are the ones who will be top dogs in business as in other affairs of life.

The question of cost comes in. It is one which requires logical investigation. The expenditure incurred in inspection, adjustment, and maintenance is a fruitful one for both consumer and undertaking. It is better for the consumers to have to pay a penny or a fraction of a penny more per 1000 c.ft. or per five therms, to secure satisfaction through an improved and continued efficiency, than to use gas wastefully. The efficiency must mean economy in the consumer's expenditure for the work done; and it is better to pay a fair price for work being well done than badly done, because the latter always means uneconomy. Taking the Glasgow figures (to which reference will presently be made), we submit that, owing to the fact that the gas consumed is used more efficiently, the consumer really spends no more on gas through the inclusion of the cost of inspection and maintenance in the charge. As to the gas undertaking, there can be no question that financially the system is a sound and profitable one. There is the additional protection against competition; there is the inducement to the increased use of gas by the consumers. This increase is no visionary thing. All those who have applied the system find that it is easier to place additional appliances in houses than it was formerly. We have to thank Glasgow for highly valuable information as to the direct costs there, against which, of course, are to be set the advantages already mentioned, but upon which no definable value can be placed. However, the direct costs, Mr. M'Lusky shows, have been diminishing with the extension of the application of the system. This is no doubt due to the gradual elimination of bad conditions, and to the growing efficiency of the men in the work. At the outset the costs were estimated at 1½d. per 1000 c.ft.; afterwards they were found to be 1¼d. Now the figure has been reduced to 0·592d. per 1000 c.ft. Of this figure, labour accounts for 0·375d.; material, 0·084d.; and overhead charges, 0·133d. Per therm the cost is 0·126d.—labour representing 0·08d., material 0·018d., and overhead charges 0·028d. It is computed that in Glasgow there are 1,250,000 appliances in 213,447 premises; and at the moment 995,038 burners and appliances are being maintained. The cost, of course, would vary with local conditions; but the Glasgow figures offer not only guidance but encouragement. They show that the bigger the maintenance scheme becomes, the cheaper it gets; they also warn that the initial figures, when the rough work of elimination and correction is being done, must not be taken as indicating the permanent figure. In the discussion on the papers, it was shown that, in two smaller towns, the cost of maintenance per 1000 c.ft. is approximately the same as in Glasgow. We are convinced that, though the cost is included in the price of gas (users of heavy consuming appliances can be justly treated by discounts), the expenditure is a profitable one for both undertakings and consumers.

Costs of Different Lights.

Gas salesmen who have been studying "An Elementary Treatise on Gas Lighting," which has been one of the features of "The Gas Salesman" for a long period, will be prepared to agree with us that not the least important of the constituents of this valuable contribution is the material which is now being presented. It deals, among other points, with the costs of lighting by the different competing agents—in which connection it is always well for the gas salesman to remember that electricity is not the only competitor. The candle, the oil-lamp, acetylene, and petrol-air gas, have their places in the realm of artificial lighting; and yet, on calculations which may be accepted as the result of scrupulous testings and computations, our contributor is able to show that incandescent gas lighting takes precedence in the amount of light afforded for a given sum, taking the charges for the agents at the figures quoted at the foot of Table 5. It is to that table that we wish to direct particular attention, because there we have concentrated the results of a laborious and time-absorbing piece of work. We believe that the table will be utilized for reference almost universally by gas salesmen, because there is not the slightest doubt it will be of considerable use to them in their work.

It will be seen that the data embrace all the competing sources of lighting—including the humble candle, the oil-lamp, acetylene, petrol-air gas, away up to the flaming or impregnated carbon type of electric lamp, as well as the much-talked-of gasfilled lamp. The light values given are for the different illuminants with the sources unscreened. But, of course, the higher one gets in intrinsic brilliancy of the source of light, the greater the necessity for screening it for the protection of the eyesight; and this protection naturally reduces the light values afforded to the user. Looking at the figures, it will be seen that the low-pressure inverted incandescent burner, using 25 B.Th.U. per M.H.C.P., will give (with gas at 8d. per therm) 6000 candle-power-hours for 1s. The advantage of the inverted preheated cluster burner is emphasized when we find that the input required is reduced to 16 B.Th.U. per M.H.C.P., and that 9375 candle-power-hours can be bought for 1s. This advance has nearly halved the margin which formerly existed between the ordinary inverted gas-burner and the high-pressure inverted burner, seeing that, with gas at 80 in. pressure, and an input of 10·5 B.Th.U. per M.H.C.P., 14,286 candle-power-hours can be purchased for 1s. The next best achievement compared with ordinary low-pressure inverted or preheated cluster burners is petrol-air gas used in inverted incandescent burners. In this case, taking petrol at 17d. per gallon, we get 5506 candle-power-hours for 1s. The best that the electric metallic filament lamp of the vacuum type can do, using 1·25 watts per M.H.C.P., is to provide 1920 candle-power-hours for 1s. (electric energy being taken at 5d. per KW.H.), which is a long way in the rear of the ordinary inverted incandescent gas-burner. The electric gasfilled lamp, using 0·66 watt per M.H.C.P., comes nearer with 3636 candle-power-hours for 1s. But it will be seen that this has to compare with 6000 candle-power-hours by the ordinary incandescent burner, and with 9375 candle-power-hours by the preheated cluster burner. In the course of the article, our contributor points out that though electric sources require to be supplied with far less heat energy than incandescent gas sources to produce equal amounts of light—for example, the gasfilled incandescent lamp expends 2·26 B.Th.U. per candle-power-hour, as against 25 B.Th.U. per candle-power-hour by the low-pressure inverted incandescent gas burner—the superior thermal efficiency of electric sources does not make electric light as cheap as gas light, simply because the transformation of electrical energy into heat is a far more expensive process than the generation of heat by burning gas.

We think enough has been said to direct attention to the special value to gas salesmen of the part of "An Elementary Treatise on Gas Lighting" which is now appearing in our pages.

"B.C.G.A." and Salesmen.—At a Midlands District Conference of the British Commercial Gas Association, which was recently held in Leicester, Mr. A. W. Smith (the General Manager and Secretary of the Birmingham Corporation Gas Department) referring to the operations of the Association, said that the Salesmen's Circles were doing wonderfully good work. It had been astonishing to see the enthusiasm of the salesmen; and this one thing alone, he declared, was sufficient to justify the activities of the "B.C.G.A."

Gas for Making Automobile Parts.—The radiator department of the Highland Park (U.S.A.) plant of the Ford Motor Company uses 270,000 c.ft. of coke-oven gas a day. It is, remarks Mr. F. I. Newton, in the pages of the "Gas Age-Record," interesting to note that the total daily consumption of the Highland Park plant is 44 million c.ft. of coke-oven gas, and 62 million c.ft. of producer gas; while the Ford Company's River Rouge plant uses about 10 million c.ft. of coke-oven gas daily. Of the total heating operations performed at the Highland Park works, 73 p.ct. are done with gas.

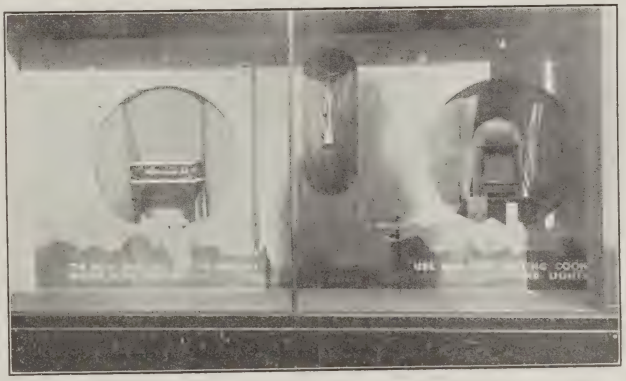
Window Displays at Greenock.

We reproduce two photographs of novel window displays in the showrooms of the Greenock Corporation Gas Department, which are excellent examples of really effective advertising.

The east window was intended to throw into bold contrast the uncivilized method of cooking in A.D. 1 and the highly civilized popular method in 1925. This effect was strikingly obtained by depicting a cave-man holding on the end of a stick a piece of meat over a fire; while in the recess of the cave, which formed the background, was a modern gas cooker. A most realistic note was struck by building the rocky background with a rugged contour before painting. Realism was carried further by having a bright red glow emanating from the embers of the fire, and by having sand and stones on the ground, and a prehistoric cudgel lying handy. A humourous touch was obtained by having the head of an ancient monster, with gaping maw, thrust over the jagged rocks, just above and to the rear of the kneeling cave-man. The only lettering which appeared was that on the cooker "A.D. 1925," and on the rocks in front "A.D. 1." The entire cave was constructed of old cardboard boxes.

The west window was designed with the purpose of setting out the "bottled sunshine" way to a clear atmosphere, and, incidentally, three of the most popular gas appliances which help greatly towards the dispersing of the obnoxious pall of smoke. A back frame was draped in blue cloth and had two 4 ft. diameter circular cut-outs and a central oval cut-out 4 ft. high by 1 ft. 6 in. wide. The circular cut-outs displayed a cooker and a fire, and the oval a chaste pendant, to advantage. At the base and in the centre of the background, a yellow sun-like half-circle embodying a small picture of a "sunshine factory" (gas-works) was interposed, and from it radiated yellow ribbons reaching across, and relieving, the background. Midway betwen the front of the window and the background, a silhouette of chimneys and buildings extended from side to side. On this black silhouette, in white letters, the following sound counsel was written: "The wise way to a smoke-free atmosphere is the gas way," and "Use 'bottled sunshine' for cooking, heating, and lighting."

COOKING IN A.D. 1 AND 1925.



SYMBOLIZING "BOTTLED SUNSHINE."

Consumers' Literature.

Among the go-ahead companies in the preparation of literature for distribution among consumers is the Croydon Gas Company. Their pamphlets and leaflets are invariably of a high-class order—the matter they contain being sound and irrefutable; they are well illustrated, and in attractiveness court and obtain admiration. Among those we have received is a gas-fire pamphlet, with a coloured picture on the outside which cannot fail to invite attention and investigation of the material and illustrations found between the covers. A useful accompaniment of most of this literature is a printed post-card addressed to the Distributing Engineer and Sales Manager of the Company, giving on the reverse side a skeleton form for the name and address of the consumer, and asking for a representative to call, on the date and hour given, with reference (as the case may be) to gas heating, cooking, &c.

Another booklet deals with "Electric *v.* Gas Cookery." On the subject of electric cooking, there is a great deal of loose talk by our rivals about gas cooking fumes spoiling food and loss of weight of joints. Some of the claims that are electrically made in the latter respect would suggest that the difference in loss of weight between the one cooking agent and the other is such that almost the whole cost of the meat is saved by using an electric cooker instead of a gas cooker. Heat is heat, however generated. Of course, among the claims of the electrical people, there is rarely any reference to the performances of the hotplate on which such a large proportion—generally close upon 80 p.ct.—of the culinary work is done. The hotplates of electric cookers are notoriously inefficient, and they quickly lose such efficiency as they originally possessed. Consequently, the high cost of the potential heat generated by a unit of electricity, together with the low efficiency in use, makes electric cooking the most expensive of all methods. In the booklet it is asked by the Croydon Gas Company: "Can the arguments used on behalf of the electric cooker and those urged against the gas cooker be substantiated?" The reply is: "We think not." And then the leaflet proceeds to recount some of the things the electric people are telling the public:

(1) That cooking by electricity is no more costly than cooking by gas.

(2) That meat cooked in an electric oven suffers far less loss of weight than a joint of equal weight (when uncooked) cooked in a gas oven.

(3) That food cooked in an internally-heated gas oven is "affected" because it absorbs the combustion products.

These typical statements are untrue. The actual fact is that one gas therm will in cooking perform the same practical service as 20 units of electricity, on the assumption that of the energy used for cooking 75 p.ct. is applied on the hotplate and 25 p.ct. in the oven. At the time this booklet was prepared, the cost of a gas therm in Croydon was 8·8d.; while 20 units of electricity, at the low figure of 1d. per unit, cost 1s. 8d. Therefore it is a fact that electric cookery is approximately two-and-a-half times as costly as gas cookery.

Then as to the weight of meat. It is pointed out (quoting *in extenso* from the booklet) that there is little or no difference in the shrinkage or loss of weight of a joint cooked to the same degree in either a gas oven or an electric oven. Meat, as is well known, contains a considerable percentage of water. The evaporation of that water during cooking operations is naturally bound to make some difference in the "before cooked" and "after cooked" weights. Independent authorities tell us that from 2 to 3 oz. in weight per lb. is so "lost" if a joint is not to be served up under-cooked. Owing to the varying nature of animal tissue in different joints and the different proportions of bone and fat contained in them, it is quite an easy matter to make very misleading "comparative" tests, and say that one system of cooking is more "wasteful" than another. The supposed "saving of meat" is, of course, simply a question of the retention of moisture in the meat. If it is desired to cook meat in such a way as to retain within the joint the maximum amount of water contained in the raw meat, this can be done as fully and as

easily in a gas oven as in an electric oven. Again, if one wishes to cook the meat more thoroughly—*i.e.*, to expel a larger quantity of moisture—this can be effected as perfectly in a gas oven as in an electric oven; but to produce the same result in an electric oven, the period of cooking must be prolonged to an inconvenient length, because the atmosphere in an electric oven remains moist through deficient ventilation. Meat cooked slowly in a gas oven does not shrink any more than meat cooked slowly in an electric oven. The various fanciful figures of "saving" are arrived at by "racing" the meat in a gas oven.

In reference to the so-called "contamination" of food by gas fumes—the two harmless substances, water vapour and carbon dioxide, both of which are evolved by food during the process of cooking—reminder is given of an article by Elizabeth Lucas, on "The Case for the Casserole," which appeared in the "Daily Mail" for Sept. 25, 1924. Among the points made by the writer were:

All food cooked in an oven loses weight, the bulk of the loss being steam; and therefore "fumes" are flowing away from the food and not into it, which is one reason why the "fumes" from gas cannot be absorbed.

To emphasize that foods being cooked are not liable to absorb "fumes," it may be mentioned that if onions are cooked in an oven at the same time that a cake is being baked, the cake does not acquire an onion flavour, although if "fumes" were being absorbed such an effect would be expected.

A further point is made of the greater flexibility of control which there is in the taps of a gas cooker as compared with the three-temperature control switches of the electric cooker.

Another pamphlet which also particularly attracts us is entitled "Model Kitchens for Modern Homes;" and in this there are photographs of typical installations of gas and coke appliances in Croydon and the district. The illustrations are highly attractive, and should be the means of greatly stimulating a widespread desire for the compact cooking and hot water installations which are shown. At the end of this revelation to householders as to what gas and coke can do is an announcement that a representative of the Company will be happy to call *at any desired time* to give personal advice, and, on request, estimates will be gladly submitted. It is also pointed out inquiries place the householder under no obligation whatever.

The Education of the Gasfitter.

By THOMAS NEWTON.

The admirable contribution on "The Education of the Gasfitter" which Mr. Rogers made at the Annual General Meeting of the Midland Association of Gas Engineers and Managers (see "JOURNAL" for March 18, p. 675) is opportune. The importance of the subject cannot be overemphasized, especially when it is remembered that progress in the future can only be made with the aid of intelligent, competent, and willing workmen.

Much well-founded criticism has recently been levelled at the present-day product of our elementary schools; and, unfortunately, such criticism is not confined to any one part of the country. The product of our elementary schools; and, raw material out of which the gasfitter is ultimately evolved. Yet what can be said in favour of this product when boys of 14 years of age, fresh from school, write "gass" for gas, "sirvis" for service, "flew-pipe" for flue-pipe, "boler" for boiler, "geeser" for geyser, "excape" for escape, and so on? In elementary arithmetic the most appalling inaccuracies are made; while grammar is a thing of the past. A schoolmaster seriously remarked to the writer some time ago that elementary education was largely a matter of fashion, and, since grammar was no longer fashionable, it was not taught in elementary schools. Be this as it may, it is high time that employers of labour demanded a much more intelligent "product" on which to commence operations.

In view of the foregoing, it is indeed questionable if boys of 14 years of age should be taken from our schools while they are so obviously unprepared to benefit from such technical education as must needs be imparted to them before they can become specialized workmen. Certainly, a much sounder elementary education is essential as a preliminary; and if the boys leave school before they receive this, it simply means that the employers must endeavour to make up for the deficiencies of the schoolmasters—and this without the schoolmasters' facilities.

The training of boys is not so simple as it used to be. Formerly, under the old apprenticeship system, a boy had little difficulty in picking-up the manual or physical part of his trade, primarily because the habit of industry was thoroughly inculcated on every possible occasion. The pride of craftsmanship was very real; and this engendered a keenness which rapidly developed into proficiency. In the old days, the keen boys found ways and means of educating themselves, both theoretically and practically, as many who now deservedly hold administrative positions can testify. Nowadays, unfortunately, the apprenticeship system has declined; and keenness among boys is not so conspicuous as it was formerly. In the conditions which prevail, boys have more facilities than formerly, yet, strange to say, they do not appreciate them as they should.

It is a common complaint that youths who under a system of apprenticeship would be both willing and energetic, are nowadays prone to be independent of the employer, because they can easily become dependent on the State. This state of affairs has ruthlessly crushed incentive where it has not completely destroyed it.

Employers have now to devise new methods and machinery whereby the youth of the industry shall be properly trained. The Birmingham system is ideal, being so comprehensive as to cover practically the whole ground; but, unfortunately, the smaller undertakings cannot hope to emulate Birmingham's example. In the first place, the smaller undertakings do not possess the necessary facilities, nor do they employ such numbers as could be formed into classes. What boys are employed are usually of different ages, and in various stages of development. In the circumstances, class tuition would appear to be precluded, and individual tuition essential. The smaller undertakings could not hope to put at a boy's disposal the same advantages as those enjoyed by the boys of (say) Birmingham, London, or Leeds. But keenness on the boy's part, and some individual tuition, would soon enable a boy to surmount many of his disadvantages. Much depends on the type of boy selected. For example, it would be an immense advantage both to the boy and his employer if the boy started to work when he was about 16 years of age, and particularly if he had spent the last two or three years of his school life at a secondary school. Such a boy would be sufficiently mentally equipped to take full advantage of the technical and scientific instruction that might subsequently be provided by his employer.

If objection be made that the age and standard of education here outlined are too high, it should be borne in mind that the gas industry has need of well-educated fitters. It is in the highest interest of the industry that the gasfitter of the future be well educated; and besides being a competent craftsman, he should also have a certain amount of scientific and technical knowledge. He must, of course, be competent to do his work; and he must also know the why and wherefore. For, after all, a gasfitter is the undertaking's representative who is always in direct contact with the undertaking's consumers, and his advice is sought—often casually, sometimes deliberately—on the hundred-and-one questions appertaining to the utilization of gas. He should be able to impart accurate information about his business in such a manner as will inspire the customer's confidence.

Here we may inquire if it would not be advisable to revive some form of the apprenticeship system for a period of four or five years; and, as some compensation for the additional time spent at a secondary school, it may be feasible to provide facilities for technical and scientific training wholly, or partly, during working hours. In these days, boys and their parents do not feel disposed to make all the sacrifices. Some undoubtedly do, but these are exceptions.

Any consideration of the education of the gasfitter would be incomplete without reference to the rewards which are offered for intelligent and competent service. Unfortunately, some are by no means tempting, and are but a meagre incentive, considering the study, time, and labour involved in becoming qualified and proficient. The bare statement that only nineteen fitters out of the whole of the British gas industry presented themselves last year for the final examination is a sufficient commentary.

Of course, it should be borne in mind that promotions to higher positions are made from the ranks of those fitters who are educationally and technically competent. This is indeed a great incentive for the few; but it will only be confusing the issue if we imagine that it is an effective incentive for the many. What seems to be required nowadays is a sufficiently strong inducement to the study that will produce highly-trained and competent gasfitters, even though they are compelled, or desire, to remain in the ranks.

Unless this attraction is offered, only a comparative few will think the effort worth while, and these few will assuredly leave the ranks at the first opportunity. The ideal to be aimed at is not to train a few fitters, offering as an inducement to study the possibility of promotion to higher positions; for in this case the ranks would be the poorer. Rather should it be to raise the standard of the fitters as fitters; and to make the training and study worth their while, apart from promotion.

In this connection, the assistance of the various trades unions would be invaluable. If a trade union is keenly interested in raising the status and wages of its members, it is only logical that it should also be equally interested in any movement which has for its object the technical training and general competency of its constituents. The gain to any industry which could agree on a working arrangement with its trade union (or unions) concerning the training and competence of the workmen engaged in that industry would be enormous.

The education and training of the gasfitter is a vital question for the gas industry; and the responsible heads of undertakings should give every possible encouragement, with a view to its solution along right lines. The old days when gasfitting was regarded as an insignificant sideline of plumbing are gone for ever.

An Elementary Treatise on Gas Lighting.

For the Student Gas Salesman.

[Communicated.]

(*Continued from p.* 58.)

Chapter 10.

Miscellaneous Considerations.

There have now been discussed the principal points connected with the progressive design of gas-lighting burners and lamps during the past century; and the primary factors essential to their efficient performance have also received consideration.

In this chapter it is hoped to deal with several other important aspects of gas lighting—matters of commercial as well as of technical significance, and including (*a*) the cost, quality, &c., of gas light as compared with electric light and other illuminants; (*b*) uses and effects of globes, shades, and reflectors; (*c*) an outline of "direct," "indirect," and "semi-indirect" systems of artificial lighting and their relative efficiencies; and (*d*) a short account of distance lighting and extinguishing equipment. With these further necessary questions disposed of, the way should be fairly clear for us to proceed with our study of the elements of illuminating engineering, uninterrupted by other by-the-way considerations.

The respective costs of producing light by different methods is an all-important question because, by reason of our standard of civilization, we in the British Isles spend annually a colossal sum of money* in purchasing artificial light in one or more of its several available forms. Now in terms of £ s. d. to the purchaser the most economical artificial illuminant is incandescent gas; and it is also the most satisfactory in regard to quality. But are the public made sufficiently cognizant of these important truths? The dissemination of knowledge on these points is one of the gas salesman's functions, for, since the sale of artificial light is still one of its trading functions, the gas industry is, of course, concerned commercially with the comparative costs of producing light by various processes in its desire to provide the public with the cheapest, best, and most reliable modern illuminant—a desire which is creditably realized.

The cost of producing light is obviously related to the particular method adopted; and it is a very variable factor, for, as will be seen later, there are many widely dissimilar methods. Before we can compare the respective costs of these methods, we must adopt a unit for quantity of light; and this unit will be the candlepower-hour—a term which means the total quantity of light radiated during one hour by a source of one candlepower intensity. It will also be necessary for us to specify, within reasonable limits of accuracy, the quantities of combustible material and electric energy required to produce our unit of light†; and further we shall have to assign to these light-yielding agents certain purchase prices. However, before tabulating these data the writer desires to say a little more about certain of the illuminants themselves.

With the ever-growing availability of public supplies of gas and electric energy at popular prices, gas and electric light have very largely superseded candles and oil lamps; and together these two former agents provide to-day the great proportion of the artificial light used in Great Britain. But there are still many occasions when gas and electric light cannot be employed; and because of this, coupled, of course, with the demand for something better than candle-flame and oil-flame light, there have been developed other and newer materials for the production of artificial light—such as acetylene and petrol-air gas—which are highly acceptable to residents in rural districts remote from gas and electric energy supply systems.

There have also been placed upon the market incandescent-oil lamps. Though we are not very much concerned in this work with the manufacture of gas and other light-producing agents, the student may, in a competitive sense, be interested to know something more about acetylene and petrol-air gas; but, deferring for the moment our consideration of these, the writer would first say a few words regarding the consumption of material by the common candle and the ordinary oil lamp. The common commercial candle gives a light approximating in intensity to that of the fundamental unit of light measurement—viz., the International Candle; and it consumes material at the average rate of (say) 120 grains (equal to 0·017143 lb.) per hour. One pound of candles will therefore yield 58·3 candlepower-hours $\left(\frac{7000}{120}\right)$.

[There are 7000 grains to the lb.] Oil lamps vary considerably in candlepower from (say) 10 to 60 (horizontal rating); and it has been stated* that as much as 100 c.p. can be obtained with carefully-designed petroleum lamps. According to the late Dr. Louis Bell† the consumption of oil per candlepower-hour may be taken as ranging from 50 to 60 grains, say an average rate of 55 grains, equivalent to 0·00119 gallon (approx.) assuming the use of kerosene weighing 6·6 lbs. per gallon. One gallon of kerosene will therefore yield 840 candlepower-hours $\left(\frac{7000 \times 6{\cdot}6}{55}\right)$.

Candle manufacture and the chemical constitution of illuminating oil were referred to in Chapter 2—see "Salesman" for Sept. 27, 1922.

Acetylene is a rather heavy and colourless hydrocarbon gas (sp. gr. = 0·92‡), having the formula C_2H_2 and being possessed, in its usually slightly impure form, of a most objectionable odour. It is a substance extremely rich in carbon, containing over 90 p.ct. by weight of this element, and has a gross calorific value of 1441 B.Th.U. per c.ft. (by test). Because of its high flame temperature§ and generous carbon content, acetylene, when burned in properly constructed burners with the correct admixture of air to prevent "smokiness," produces a steady flame which by virtue of its brilliant white light far surpasses the duty given by any other flame illuminant. When water is brought into contact with calcium carbide, there are formed, according to the following reaction, lime and acetylene gas:

$$\underset{\text{calcium carbide}}{CaC_2} + 2\,\underset{\text{water}}{H_2O} = \underset{\text{lime}}{Ca(OH)_2} + \underset{\text{acetylene}}{C_2H_2}$$

[Strictly speaking, this equation is true only of *pure* acetylene.]

Various foreign substances, due to chemical impurities very generally present in commercial carbide, are found in acetylene; and it is therefore necessary to purify the gas as much as possible by washing it with water. For the supply of acetylene to isolated premises, several makes of reliable automatic and non-automatic generating and purifying plants are available in a variety of sizes according to the number of lights they are required to serve. The selected plant is housed outside the main-building, and it supplies gas, usually at a pressure of 3 to 4 in. of water, through a system of house-piping (smaller in diameter than that commonly used for town gas) to the required lighting points. Preferably, acetylene flame burners should be of the air-injection type; and these are made in a variety of sizes, taking from 0·25 c.ft. to 1·25 c.ft. per hour, and yielding an average duty as high as 40* candles per c.ft. per hour (horizontal rating). We can thus assign to acetylene flames used for indoor lighting a commercial efficiency of 0·025 c.ft. per candlepower-hour. In actual practice the average yield of acetylene per pound of calcium carbide acted upon is of the order of 4·5 c.ft.† Hence 1 lb. of this material will yield sufficient gas to give 180 candlepower-hours (4·5 × 40); and 1 ton will yield (say) 10,080 c.ft. of gas, having a light equivalent of 403,200 candlepower-hours. The weight of carbide required per candlepower-hour is therefore approximately 0·0055 lb. Various attempts have been made to apply the incandescent mantle principle to acetylene by burning the gas in specially-designed atmospheric burners; but several practical difficulties have asserted themselves. The tiny burner orifices are apt to get choked, and satisfactory burner performance calls for the manufacture of highly-purified gas and for its distribution at a fairly high and constant pressure—say, about 6 in. of water. Provided the acetylene can be properly "bunsenized," the very high flame temperature which results can be used to economical advantage with small mantles of robust manufacture; and it has been stated that inverted incandescent acetylene burners—nominally of 60 c.p. intensity—realize the remarkable efficiency of 100 c.p.‡ per c.ft. per hour. This is equivalent to 0·010 c.ft. of gas, or to 0·0022 lb. (approx.) of calcium carbide per candlepower-hour. One pound of carbide will therefore yield 450 candlepower-hours (4·5 × 100) by the incandescent mantle system. Where portability is a necessary requirement, acetylene is a convenient illuminant, as it can be stored with comparative ease and safety by dissolving it in acetone—an organic liquid substance which "takes up" twenty-five times its own volume of acetylene at normal temperature and pressure, and about ten times this quantity under a pressure of 150 lbs. per sq. in. at the temperature of 15° C. In calculating the cost of producing light by means of acetylene, one must, of course, bear in mind not only the material from which the gas is made, but also the capital outlay on generating equipment, depreciation of plant and attendance charges, including handling and storing expenses. These

---

* As far back as 1906 the late Prof. Silvanus P. Thompson, D.Sc., F.R.S., in the course of a lecture delivered at the York Meeting of the British Association, said that "we in Great Britain spend annually a gigantic sum, estimated at from £10,000,000 to £20,000,000, in manufacturing for ourselves such artificial light as our civilization demands."

† This has already been done in the case of incandescent gas burners: but the data given in Table 2 are recapitulated in Table 5, for the sake of completeness.

* See "Modern Illuminants and Illuminating Engineering," by Gaster and Dow, 1915.

† See "Art of Illumination," by Dr. Louis Bell, 1912.

‡ Air as standard—*i.e.*, 1·0c.

§ The ordinary flame temperature of acetylene is in the neighbourhood of 2200° C. (Bell.)

* This is the figure which is usually taken when estimating for generator capacity. [Acetylene burner data as given in A. Blok's "Elementary Principles of Illumination and Artificial Lighting," 1914.]

† The theoretical yield of C_2H_2 per lb. of CaC_2 is 5·6 c.ft.

‡ Horizontal candlepower rating, presumably.

TABLE 5.—*Statement of Comparative Costs of Manufacturing Light by Different Methods.*

Method of Manufacturing Light.	Weight or Volume of Material, No. of B.Th.U. and Quantity of Electric Energy Required per Candlepower-Hour (Approx.).	Cost. Pence per Candlepower-Hour (Approx.). (*a*)	Cost. Pence per 1000-Candle-power-Hours (Approx.). (*b*)	Cost. Candlepower-Hours Purchased for 1s. (Approx.). (*c*)
By (1) candle (ordinary commercial type)	0·017143 lb. (horizontal rating)	0·085715	85·715	140
,, (2) oil—				
(*a*) Domestic wick lamp	0·00119 gall. (horizontal rating)	0·01666	16·66	720
(*b*) ,, incandescent mantle lamp*	0·000216 ,, ,, ,,	0·003024	3·024	3,960
,, (3) town gas—				
(*a*) open flame burner	0·4 c.ft.†	0·01200	12·00	1,000
(*b*) low-pressure upright incandescent burner	45 B.Th.U. (m.s.c.p. rating)	0·00360	3·60	3,333
	34 ,, (horizontal ,,)	0·00272	2·72	4,412
(*c*) ,, inverted ,, ,,	25 ,, (m.h.c.p. ,,)	0·00200	2·00	6,000
(*d*) ,, ,, ,, * pre-heated cluster-burner	16 ,, (,, ,,)	0·00128	1·28	9,375

,, (4) acetylene—				
(*a*) open-flame burner	0·025 c.ft. C_2H_2; or 0·0055 lb. CaC_2 (horizontal rating)	0·01100	11·00	1,080
(*b*) inverted incandescent burner	0·010 c.ft. C_2H_2; or 0·0022 lb. CaC_2 (horizontal rating)	0·00440	4·40	2,700
,, (5) petrol-air gas used in inverted incandescent burner	0·000128 gall. (m.h.c.p. rating)	0·002176	2·176	5,506
,, (6) electric energy—				
(*a*) carbon filament lamp (low efficiency, 800 hours' life type)	4·05 watts (m.h.c.p. rating) equivalent to 13·85 B.Th.U.	0·02025	20·25	592
(*b*) ,, ,, ,, (high efficiency, 400 hours' life type)	3·52 watts (m.h.c.p. rating) equivalent to 12·04 B.Th.U.	0·01760	17·60	682
(*c*) metal filament lamp (vacuum type)	1·25 watts (m.h.c.p. rating) equivalent to 4·27 B.Th.U.	0·00625	6·25	1,920
(*d*) ,, ,, ,, (gasfilled type)	0·66 watt (m.h.c.p. rating) equivalent to 2·26 B.Th.U.	0·0033	3·30	3,636
(*e*) arc lamp (ordinary or plain carbon type)	1·25 watts (m.s.c.p. rating) equivalent to 4·27 B.Th.U.	0·00625	6·25	1,920
(*f*) ,, ,, (flaming or impregnated carbon type)	0·265 watt (m.s.c.p. rating) equivalent to 0·91 B.Th.U.	0·001325	1·325	9,056

* Upright mantle type. A much higher efficiency is claimed on behalf of certain oil-vapour inverted mantle lamps of relatively high luminous output (say, 300 c.p. upwards). These high-power incandescent oil lamps are spoken of in the text.

† 16 c.p. quality—old illuminating power standard. Price (say) 2s. 6d. per 1000 c.ft.

In the table, columns (*a*) and (*b*) have been calculated from the quantities given in the first column; but in certain cases the values in column (*c*) have been determined on the basis of the number of candlepower-hours provided by 1 lb. of candles, 1 gall. of oil, &c., at the listed prices. Since, in the reduction of these values from candlepower-hours per lb. or gallon to the decimal fractions of the lb. and gallon per candlepower-hour, some of the values in the first column have had to be approximated to restrict the number of figures, one or two of the end column values (*c*) will differ very slightly from the tabulated values if one evaluates them on the basis of the approximate quantities in columns (*a*) or (*b*), because, as already explained, the figures in column (*c*) have been derived from the number of candlepower-hours (as mentioned in the text) bought in the form of 1 lb. of candles, 1 gall. of oil, &c.

NOTE.—The monetary values in the above table are related to the following fair average purchase prices of the materials and electric energy involved in the light-making processes under review:

(1) Commercial candles	per lb. 5d.	(4) Calcium carbide	per lb. 2d.
(2) Kerosene oil, flash-point 110° Fahr.	per gall. 14d.	(5) Petrol	per gall. 17d.
(3) Town gas	per therm 8d.	(6) Electric energy	per kilowatt-hour 5d.

latter are constituent items of "all in"* cost, and they apply equally—and must not be overlooked—in the case of petrol-air gas lighting, to which method we shall now make brief allusion.

Petrol-air gas is simply air saturated with the vapour of volatile hydrocarbons, varying in specific gravity from about 0·68 to 0·74, and forming the substance known commercially as petrol. In Great Britain the proportion of petrol vapour to air is lower than that often used in America, and it seldom exceeds more than about 6 p.ct. by volume. Such a gas would be regarded in British practice as relatively rich, as in a number of plants only 1·5 to 2 p.ct. of petrol vapour admixture is employed.† There are many suitable machines available for the manufacture of petrol-air gas, and they are simple in operation—consisting essentially of a form of carburettor and a storage holder which delivers the gas to the house piping system usually at a pressure of 1·5 to 2 in. of water. "Lean" petrol-air gas as generally manufactured in this country gives very satisfactory results when used in conjunction with incandescent mantle burners. The manufacturing plant is usually installed in an outhouse; and the premises are carcassed much in the same way as for town gas.‡ The size of incandescent petrol-air-gas burner commonly used approximates to that of the town gas "bijou" burner; and there has been claimed for it a luminous output of from 70 to 80 c.p. (with new mantle) for a consumption of $\frac{1}{10}$ gallon of petrol per hour.* It would seem, however, that these values of luminous intensity and petrol consumption relate to horizontal candlepower; and if we think in terms of m.h.s.c.p. it is fairly evident that the average performance of such a burner would not be more than about 60 c.p. On this rating the petrol consumption per candlepower-hour is approximately 0·000128 gallon—the quantity suggested in Table 5 and derived from the figure of 7800 candlepower-hours per gallon.†

Oil lamp design has undergone a noteworthy change during the past fifteen years or so. Oil has altered in character from a flame illuminant to an incandescent radiant, consequent upon an improved method of burning it whereby the old-time wick can be superseded by the incandescent mantle. There have been available for some years various types of upright and inverted self-contained incandescent oil-lamps in which petroleum is vaporized and mixed with a generous quantity of air to form a clean-burning non-luminous flame possessed of the requisite temperature to render mantles incandescent. One particular make of domestic incandescent oil lamp equipped with a rather "squat" upright mantle is stated to yield 80 c.p. (presumably this is the horizontal candlepower) and to burn a mixture of 94 p.ct. (by volume) of air and 6 p.ct. of oil vapour. The oil consumption of such a lamp appears to be of the order of 10 grains per candlepower-hour; and, therefore, assuming the use of kerosene weighing 6·6 lbs. per gallon, 1 gallon of oil provides a lighting service of 4620 candlepower-hours.* The design and performances of one or two types of high-power inverted incandescent oil lamps are interesting matters which are discussed in the comprehensive work of Gaster and Dow.† These gentlemen mention that claims of the order of 14,000 candlepower-hours per gallon of oil—and even as high as 18,000 candlepower-hours—have been made on behalf of certain large lamps; and they also refer to the fact that on the Continent the principle of the incandescent mantle has been applied to burners consuming alcohol.

* The prices of oil, gas, and electric energy cover materials and manufacturing costs (they are, as it were, "prices delivered"), whereas the prices of acetylene and petrol-air gas, as given in Table 5, are exclusive of manufacturing charges.

† A mixture of 2 p.ct. of petrol vapour and 98 p.ct. of air would have a calorific value of 71·6 B.Th.U. per c.ft.

‡ Where "lean" petrol-air gas is used, rather larger pipes are usually run than those generally provided for the supply of town gas for incandescent lighting.

* See data given in "Modern Illuminants and Illuminating Engineering." (Gaster and Dow.)

† If $\frac{1}{7\frac{1}{2}\frac{1}{0}}$ gallon per hour yields 60 c.p., 1 gallon will yield 60 × 130 = 7800 candlepower-hours.

* $\frac{6\cdot6 \text{ lbs.} \times 7000 \text{ grains}}{10}$

† "Modern Illuminants and Illuminating Engineering."

(To be continued.)

Factors in Writing Selling Letters.—In a contribution to "System," Mr. J. H. Picken sets out the following views on the drafting of selling letters: The opening must appeal to something interesting in the mind of the reader, and must contain the proposition that is the subject of the letter. It must have a "leading" quality (an appeal to the curiosity), and must conform with the six principles of business letter writing. These are: (1) Do not arouse debate or denial. (2) Do not "side track" the prospect's interest by lack of continuity. (3) The letter must be easy to read. (4) Tell a complete story. (5) Stress advantages gained, not disadvantages avoided. (6) Avoid as far as possible propositions calling for a choice by the reader.

B.C.G.A. Gas Salesmen's Circles.

Southern District—London Area.

The April Meeting of this Circle was held on the 7th inst.—Mr. Stephen Lacey, Chairman of the Circle, presiding.

LOCAL PUBLICITY.

By W. D. Elson, of the "B.C.G.A."

Need for Local Publicity.

It is an accepted axiom that, in these days of keen competition, a business cannot stand still. It must either progress or retrogress; and, so far as the gas industry is concerned, publicity coupled with good service provides the chief means of development. The possession of a virtual monopoly has a tendency to restrict effort until it is recognized that, in effect, a gas undertaking is in a position of trust in relation to the community, and possesses a responsibility for demonstrating the services it is in a position to render to each individual member of that community. The success of each undertaking is in direct proportion to the efforts it makes to achieve that object. The last decade has seen the industry progress with great strides, but there still remains a wonderful field for development; and organized effort is the sure means by which success can be achieved. Competition there must be, and in ever-increasing strength; but this should be welcomed rather than deprecated, promoting as it does a healthy rivalry and a spur to increased effort and a security against stagnation.

Local Publicity Defined.

Local publicity may briefly be described as the seed which must be sown if a harvest is to be available for the salesmen's reaping, and, to extend the metaphor, the success of the harvest is directly dependent upon the care with which the seed is sown, and the crop tended and nursed until it reaches fruition. Definitions of "publicity" are many and varied; but an excellent description appeared in an electrical journal a short time ago:

> "Publicity signifies an attitude of mind as well as action; it signifies enthusiasm, energy guided into the right channels, concentrated effort for the general, rather than the individual, good—and, therefore, unselfishness."

Avenues for Development.

Perhaps it would be as well now to enumerate the various ways in which local publicity can be carried out. I will afterwards deal with each subject as briefly as possible. They are as follows: Local Press, showroom window displays, circular letter or postal canvassing, literature, hoardings, cookery demonstrations, health weeks, lectures, carnivals, sales weeks, exhibitions, parish magazines, competitions, reductions in price of gas, remembrance publicity.

Press Advertising.

In contracting for space in the local Press, endeavour should be made to secure what is known as a "solus" position, if possible—that is, one away by itself, and not hemmed-in by an assortment of heavily-leaded advertisements of all descriptions, which are so common a feature of many local newspapers, and which kill the effect of any decent advertisement, however carefully it may have been prepared. The use of a distinctive symbol in advertisements results in the added advantage of making them easily recognizable, and adds to their attractiveness, provided, of course, that the advertisement is at the same time well displayed.

The preparation of an advertisement is not the simple matter it seems at a casual glance. On the contrary, it is a highly specialized business, and many a valuable space is wasted by carelessly-displayed advertisements which ninety-nine people out of every hundred will not take the trouble to read. A common error is in trying to say too much. Many points can be made by inference quite as effectively as by a full statement. Remember that, as a majority of people do not buy newspapers to read advertisements, you must make your announcement stand out to attract their attention.

A few general observations on the preparation of advertisements may perhaps prove of interest to you, and helpful when you have occasion to draft advertisements for your undertaking's local publicity. A good advertisement may be said to do four things:

1. Attract attention.
2. Arouse interest.
3. Create desire to possess.
4. Ensure the decision to purchase.

Attention may be attracted by

(*a*) Illustration.
(*b*) Caption (or headline).
(*c*) White space.

While an illustration is not essential to the "pulling" power of an advertisement, it nevertheless frequently adds to its attractiveness; but it should be emphasized that, if an illustration is decided upon, it should suit the copy, and not the copy the illustration.

Blocks for the illustration of advertisements are of two kinds, half-tone and line; and the use of them generally depends upon the texture of the paper upon which the advertisement is to be printed. The former are reproductions from photographs or wash drawings, and the latter from pen and ink sketches. Half-tone blocks are necessary for printing on paper with an art or a smooth surface, and vary in respect of their "screen." The screen of a block is the "pin-head" effect produced in its manufacture; and its fineness is dependent upon the number of "pin-heads" to the square inch. These can be easily seen in a newspaper illustration, in which the screen is particularly coarse when photographs, for instance, are reproduced. For illustrating on newsprint and other coarse papers, line blocks are necessary. The "B.C.G.A." have a wide range of designs on all subjects, blocks of which can be obtained at practically cost price; no charge being made in respect of the cost of the original drawings.

So far as the caption is concerned, this, of course, depends to a great extent upon the copy, and can be either an actual part of the text, set in bold type, or a "catchy" phrase. It is a good practice to lift a line out of the text itself, which contains the gist of the subject, and, if necessary, contract it, as the caption should be brief and to the point.

Opinions differ as to the value of white space in advertisements, some inclining to the view that space is expensive, and should not be wasted, and also that a good copy writer should be capable of making an advertisement effective through the use of a strong caption and illustration. On the other hand, it cannot be denied that a good margin of white space does make an advertisement prominent.

Interest is aroused by the wording of the copy, which should receive careful attention. When writing copy, it is helpful to bear in mind that you are writing not for possibly thousands of newspaper readers, but to each individual. Copy must carry conviction, otherwise it fails.

Desire to possess. This stage of the appeal should demonstrate to the readers the benefits that will accrue from the use of the apparatus in question, and should consist of real selling talk.

Decision to purchase is the test to which the three other considerations are subjected, and it is upon this test that the success of the advertisement depends.

This is the frequent cause of advertisers' stunts—as, for example, the printing of a discount coupon, "money back if dissatisfied" guarantee, or "short-period" offers; but the advertisement should be strong enough in itself at least to bring inquiries.

Type.

The choice of type is a difficult question, and must depend to a great extent upon the fount possessed by the printer, as this generally is restricted so far as publications of a purely local character are concerned. The best course is to indicate, by a layout, the desired appearance of the advertisement, and leave it to the printer to follow as closely as possible.

Persistency is the secret of success in advertising; and while it is not often possible to trace business resulting from one particular advertisement, it is the cumulative effect of a well-devised and consistent advertising campaign which ensures the most satisfactory results. The national propaganda of the "B.C.G.A." prepares the way; and the gas undertaking that supplements this effort by local publicity will reap the greatest benefit. The "B.C.G.A." are always ready and willing to help and advise in these matters, and will, in fact, handle the whole of a local advertising contract from beginning to end, if desired.

It is always politic to cultivate good relations with the local Press. Of course, a consistent advertising campaign is an effective means to this end; but there are other opportunities which present themselves, of which it is worth while to take advantage. It is frequently possible to arrange for brief articles describing the activities of the undertaking to be inserted as news items. This is always good publicity.

Much can be said in favour of publishing advertisements of a topical nature, describing the history and growth of the undertaking, additions to its manufacturing plant, the amount of gas made, increased consumptions, amount paid in rates, number of men employed, and other such information which will give the public a closer insight into its working, and certainly tend to improve the mutual relationship.

Showroom Windows.

I do not propose to say much on the subject of showroom window displays, as this has already been discussed at previous meetings of the Circle, and will also receive attention at the final meeting of this session. There is not the slightest doubt, however, that a showroom window is a wonderful potential business getter; and here again a considerable amount of ingenuity is necessary if the maximum results are to be secured. The secret, as with Press publicity, is a regular change of appeal. There is nothing so deadening as monotony. The "B.C.G.A." provide at a nominal hiring charge a regular change of showroom window displays.

A well-lighted shop frontage after business hours has a strong advertising effect,

and enables a good window display to "work overtime," by attracting the attention of those of the public who do not have the opportunity of seeing the shops during the day. The practice of the large West-End firms illustrates this point. By such a lead, moreover, local shopkeepers may be induced to follow suit.

Postal Canvassing.

Postal canvassing is one of the chief avenues for local publicity, but one of the most neglected. It requires a good deal of foresight and careful organizing, if it is to prove a success; for it serves to bring your message immediately to the attention of the prospective consumer, where possibly other forms of advertising may fail. It is important for the success of any scheme of postal canvassing that the letters should convey an impression of personal correspondence, and not as being part of a general appeal. The letter takes the place of a personal interview; and this consideration must be kept in mind in its preparation. The proposals should be presented as much as possible from the consumer's point of view, which is the only sure way of securing interest. The paragraphs should be comparatively short, and the general appearance of the letter well balanced, with a good margin on either side. A distinct reference should also be made to enclosures. This can appear at the head of the letter or in the margin opposite the reference to them.

Of the two chief methods available for producing circular letters, the most satisfactory is the "Multigraph," which imitates typewriting. With care, it is possible to produce facsimile letters which it is difficult to distinguish from those individually typewritten. Particular attention should, however, be paid to the filling-in of each name and address, which is an essential part of any circular letter, but which will almost entirely destroy its value if carelessly done. Most local typewriting bureaux are able to supply such circular letters, but the "B.C.G.A." also possess the necessary equipment, and will be pleased to submit particulars to members interested.

A rather amusing reference to the subject of composing circular letters appeared in a business magazine recently, under the heading "How long does it take to write a circular letter?" "A man of ability might possibly complete the letter in a day; a man of ordinary ability could write it in half a day; and any fool could write it in half an hour."

Internal organization must be the basis of any scheme of postal canvassing. For example, the existing possibilities for securing new business should be established in the first place, otherwise a considerable and unnecessary amount of wasted effort results, as well as annoyance to the consumer, who is already using gas for the purpose to which the canvassing is directed. The Sales Organization Scheme prepared by the "B.C.G.A." provides not only for the censussing of the district, but also for the examination and recording of opportunities for business. This record is valuable to the undertaking, and acts as the starting point for any campaign.

Complaints.

I will interpose here a brief reference to complaints, which can be reduced to a minimum by a carefully-devised and regular postal campaign. The absence of complaints by no means indicates that your consumers are satisfied. There are no doubt many instances where gas appliances have been superseded through unsatisfactory service, where an inquiring canvassing letter would have elicited information as to the service being given by existing appliances, thus enabling the undertaking to rectify matters and, possibly, secure new business. The truism that the best advertisement is a satisfied consumer is in danger of becoming hackneyed through constant use, but it is too important to be overlooked when local publicity schemes are under consideration.

It cannot be too strongly emphasized that the completion of an installation should not be looked upon as the end of a transaction. It is essential that the matter be followed up at a later date, with a view to ascertaining whether the installation is giving entire satisfaction. This, with an occasional postal inquiry, will prove effective in the development of goodwill.

The literature question is closely bound up with postal publicity; and a piece of advertising literature should be enclosed with every letter sent out by the gas undertaking. If the subject be of only a formal nature, such as an acknowledgment, for which a postcard is sufficient, then the reverse of that postcard should bear an advertisement.

Of the two chief kinds of literature, a booklet is distinct from a catalogue in that it is written attractively in the endeavour to interest the recipient in the general advantages of the particular subject dealt with, while the latter contains actual details, illustrations, and prices of appliances, &c. There are two distinct methods of writing a booklet—it may be either brief, putting the facts concisely with little elaboration, or a fully descriptive story. Gas literature especially can be effectively written in either style; but it must be always borne in mind that literature takes the place, temporarily at least, of a salesman, without the advantages of personal contact he possesses, and that, in consequence, additional effort must be made in its preparation, to overcome this handicap. In one direction, however, literature possesses an advantage over the salesman in that it is consistent in its effectiveness. Once written, it continues to present its story with unfailing regularity, so long as it remains in circulation.

The general outline of the chief considerations in connection with the layout of advertisements, to which reference has already been made, applies also in principle to the preparation of a booklet. Illustrations contribute a great deal to its effectiveness, and help to relieve the otherwise heavy appearance of the printed matter.

Showrooms should be plentifully stocked with literature, preferably on tables at which consumers can sit, if their stay in the showroom is likely to be in the least protracted.

An essential point in considering these four primary avenues for local publicity is "concentration." For example, if the intention is to develop the sale of gas water heaters, then the Press advertising, showroom window displays, postal canvassing, and literature distributed should be co-ordinated during the period of the campaign. It is far better to focus the attention of the public upon one thing at a time than to generalize; and it is only necessary to put this theory into practice, to realize the pulling power of such a campaign.

Educational Propaganda.

There has been a considerable development in recent years in the direction of educational propaganda, particularly so far as local exhibitions and cookery demonstrations are concerned. Of course, the former calls for a heavy amount of detail work in organization; but excellent results are secured if the arrangements are carried through with thoroughness, and it will usually be found that the gas appliance manufacturers are willing to give their wholehearted co-operation to ventures of this description.

Competitions in cake or bread making, &c., add considerably to the attraction of gas exhibitions. Cookery demonstrations have come to be looked upon as an essential feature of any exhibition; but it is also becoming a common practice to hold a series of demonstrations, generally for a period of one week, in a suitable hall. Sometimes the undertaking's showrooms will be found suitable for the purpose, which is, of course, an added advantage. The demonstrator should work to a prearranged schedule; and a programme containing a note of the dishes to be cooked should be circulated with the invitations.

Local sales weeks also provide an excellent opportunity for the development of business. It is usual on these occasions to offer a small discount off list prices for appliances, and to fix them free of cost up to a stated maximum of piping, anything exceeding that amount being charged at cost. This practice, it might be mentioned, is often adopted during the period of exhibitions.

During local shopping weeks it is a frequent practice to arrange a procession of decorated cars in the cause of charity; and it is good policy for the gas undertaking, as an important member of the business community, to take its part. Considerable ingenuity has been exercised on occasions in the designing of these carnival cars. A "live" display is usually most effective—the gas being carried in cylinders. A good idea is to cook pastries during the procession, selling them *en route* for the benefit of the charity in question. The "B.C.G.A." have an extensive file of photographs of decorated cars of all descriptions, and, if desired, a selection of these will be forwarded as a guide to any undertaking.

In local health weeks a further valuable opportunity for educational propaganda occurs, particularly as health authorities and other influential local residents take a keen interest in them. The industry has a strong plank in the subject of smoke abatement and the allied question of coal conservation upon which to base its propaganda on these occasions; and these, coupled with publicity emphasizing the hygienic aspect of the use of gas, secure particular attention in such circumstances.

By no means the least valuable opportunity for education work lies in the direction of giving lectures before local institutions such as chambers of commerce and other organizations. We are apt to forget the wonderful story that lies in the manufacture of gas and the utilization of its many bye-products. The smoke abatement and bye-products section of the Gas Exhibit at Wembley bore ample evidence of the interest of this story to the public. In addition, there are innumerable industrial uses of gas which are well worth the telling.

Reductions in the Price of Gas.

On those occasions when the price of gas is reduced an opportunity presents itself for shouting the praise of gas from the housetops. A reduction in price is an event of some moment to a large proportion of consumers; and the gas undertaking should make every effort to ensure that the amount of money that nominally would be saved by consumers is expended with interest in the extended use of gas. A printed announcement of the proposed reduction should be circulated with the quarterly gas accounts, and also distributed by the meter collectors. The leaflet should carry a description of the various domestic uses for gas; and no effort should be spared to emphasize the increased advantage that consumers will secure from the greater use of gas appliances.

Outdoor Publicity.

The display of posters on hoardings is a particularly valuable form of local publicity. The poster is always working; its appeal is insistent, and, by its colour appeal and strength of display, compels attention and stimulates memory. The most striking points in its favour are that it is seen by everybody, it is an ever-present reminder of the position of your showrooms, and it has no waste circulation.

An important consideration, however, is the selection of sites. The best, of course, are those in the main shopping thorough-

fares, on station platforms, and at other places where people congregate. Street corner positions should be avoided. Posters quickly deteriorate from exposure to the weather, and care should be taken to ensure that they are maintained in good condition. In the case of contracts, this responsibility falls on the bill-posting contractor.

Further opportunities for outdoor publicity are provided by the gas undertaking's transport vehicles. Some undertakings go so far as to make use of their gasholders for the purpose.

Remembrance Publicity.

This term signifies the distribution of pieces of advertising material of a more or less lasting nature, as, for example, playing cards, book matches, calendars, diaries, &c., which are acceptable gifts, and, if judiciously issued, promote valuable goodwill, particularly among local officials, without necessarily being costly. This has been proved by the number of letters which the "B.C.G.A." have received from members, giving details of the appreciative thanks they have received from many of those among whom such material has been distributed.

Every endeavour should be made to cultivate good relations with local authorities and others who help to mould public opinion. Goodwill in these quarters is often invaluable, and its influence is apparent in unexpected ways in dealing with the public. Doctors particularly can be excellent salesmen of gas for heating, by installing gas fires in their waiting and consulting rooms.

In conclusion, it should be emphasized that the basis of any successful selling effort is essentially good service, which comprises the supplying of gas of suitable quality and at adequate pressure, the installing of the most economical appliances, and the constant maintenance of those appliances in efficient working order.

Discussion.

The Chairman remarked that the paper covered a wide field, and there was plenty of scope for discussion. Mr. Elson had given them a list of methods of publicity; and he (the speaker) queried the value of the parish magazine as a medium for advertisement. He had been interested in Mr. Elson's reference to the subject of composing circular letters, when it was said that a man of ability might possibly complete the letter in a day. This reminded him of a remark made by Mr. J. G. Clark, who, on presenting a paper, apologized for its length, saying that unfortunately he had not had time to write a shorter one.

Mr. F. R. Pickering (Rochester) said that Mr. Elson had given them a paper in which there was a mass of detail which would prove of great help to them all. In his opinion it was an excellent idea to have some device by which advertisements could immediately be recognized. For example, on every advertisement issued by his Company appeared a small silhouette profile of the district, underneath which was written "Gas Service." Consumers, by this simple device, recognized the Company's advertisements at once; and the local touch added to the interest aroused. Mr. Pickering laid stress on the selection of good type for advertisements. As for personal letters, much more could be done than was at present accomplished in this direction; and the "B.C.G.A." were ready to help any undertaking with this work. He thought that the gas industry was very much behind other industries and business firms in the matter of poster advertisement. Most of the posters issued were poor; and they could certainly do more at Rochester if good ones were available.

Mr. J. C. Walker (Hon. Secretary of the Circle) said that Mr. Pickering's remarks about posters were very much to the point. The whole thing was a question of money; and the gas industry was not willing to spend the necessary amount—it was not educated up to the use of posters. As a matter of fact they had not yet reached the stage when the industry as a whole was enthusiastic for advertisement. It was true that the cost of production was heavy; but he hoped the time would soon arrive when the industry would take such an interest that poster advertisement would become a real force in the publicity campaign.

Mr. Pickering suggested that it was a good plan in newspaper advertising to have a standard frame for the block.

Mr. W. H. Beckett (Gas Light and Coke Company), after referring to the help afforded by Mr. Elson's paper, said that, when undertaking advertisement work, they should decide beforehand to advertise those things which would yield a quick return. In his opinion the ordinary poster contained far too much detail. The fundamental characteristic of a good poster was that it aroused a desire to possess the means of attaining the comfort or beauty expressed. They should put a premium on their goods.

Mr. R. P. Ardley (Gas Light and Coke Company) made some interesting observations on postal advertising. Even with such work as calendar publicity they had obtained direct replies, resulting in the installation of 6 cookers, 8 water heaters, and 21 other appliances; the cash value of the whole being £119. It was necessary to know what apparatus the consumers had. They had recently canvassed many districts. For example, in the Kensington district they had dealt with 2238 addresses—equivalent to two years of one man's time. The direct result from this offer of service was the installation of 31 cookers, 12 water heaters, 268 ordinary heaters, and 129 miscellaneous appliances. In addition the examiner had brought in for overhaul 785 appliances—all of which were charged jobs—and maintenance contracts for 1507 stoves and 51 lights. Following this examination scheme, 50,000 letters were sent. If they received 1 p.ct. replies, this paid the expenses of the scheme; and the remaining 99 p.ct. produced indirect results.

Mr. W. A. Bishop (Croydon) remarked that they should take the public into their confidence, not as a favour, but as their right. It was necessary to have a sympathetic public opinion; and for this reason they should welcome complaints. Referring to Mr. Elson's list of the avenues of publicity, he said that at Croydon they made considerable use of the local Press, and found the 8-in. double-column advertisement the most suitable. Many "B.C.G.A." blocks fitted this space. In addition they had seasonal campaigns during which time they sent circular letters and held cookery demonstrations, &c. From parish magazines the results were very poor, but "remembrance publicity" was useful. He thoroughly agreed with Mr. Elson as to the use of good type. In the headlines of advertisements the word gas should be incorporated. A good advertisement said little, was simple, but impressed strongly. They should not disregard the value of light as an advertising medium. At Croydon they had recently fixed six lamps above the façia of a clothier's shop. As a result of the first week's use, the turnover of this consumer's business increased by £100.

Mr. J. Davis (Sutton) said that good publicity was essential, but its value was negatived if it was not backed-up by good service. He asked Mr. Elson what was his idea of the worth of kinema advertising.

Mr. E. L. Oughton (South Suburban) suggested that it would be a good plan if advertisements were inserted in the newspapers on a definite day each week. The public would then come to look for these on a particular day. As for parish magazines, in provincial districts these were often the means of retaining the lighting of churches, &c., or of re-equipping these buildings. It should be remembered that local publicity was local; and that what proved to be a good scheme in one district might be ineffective in others. Showroom window displays, for instance, should be designed to meet the conditions of the locality, and above all should be varied as much as possible. Mr. Elson had stated that literature possessed an advantage over the salesman in that it was consistent in its effectiveness. He (the speaker) suggested that nothing could take the place of a good salesman.

Mr. W. L. Westbrook (North Middlesex) emphasized the need for advertising such facts as that the use of gas resulted in a saving of labour. He supported Mr. Bishop in his contention that brevity was desirable in all advertisements. Postal canvassing, he thought, could be carried too far, till it became a nuisance. In his Company the meter inspectors distributed literature, and this was found to be beneficial. The use of rubber stamps on accounts, &c., was also of considerable value.

Mr. F. D. Medcalf (London) suggested that the use of distinctive symbols could be carried further than local advertising. For example, price cards could embody a symbol which would then link-up with local advertising.

Mr. A. J. Garward (Portsmouth) said that the main point of an advertisement should be incorporated in the catch heading, and the case should be stated with as much brevity as possible. When the advertisement appeared on a page on which there were others, it was advisable to give due consideration to the proper employment of white space. This was done at Portsmouth. There was no question that all undertakings should welcome complaints. Regarding poster advertising, he wondered whether the manufacturers of appliances had been approached with a view to co-operation with gas undertakings for this purpose.

Mr. R. J. Behenna (London) remarked that it was impossible for many consumers to visit the showrooms during business hours; and he suggested that it would be a good plan if the showroom window was lighted "after hours," and the price cards had catalogue numbers on them. The would-be purchaser could then write a number on his visiting card, which he could drop into the letter box. The inquiry could then be followed-up.

Mr. Walker, referring to Mr. Oughton's remark about inserting advertisements on definite days, said that this was all a matter of cost. Mr. Davis had rightly stressed the importance of having one's house in order before attempting to advertise. Good service was an essential. It was disheartening to realize that the industry spent only 0·002 p.ct. of their income on advertising; for there was no doubt that they would reap the benefit of more extensive and better publicity. All advertisements should be truthful; and over-statements should be made neither in conversation nor in the Press, otherwise the public would lose confidence in them. Experience proved that it was false economy to reduce advertising during busy periods. Advertising was like the fly-wheel of an engine—it absorbed a lot of energy in starting, but required much less to keep it in motion. Advertisement, he reminded them, was by no means confined to local newspapers. Everything that went out from the undertaking—from the human beings to the gas accounts—constituted an advertisement—good or bad. Everything in connection with a gas undertaking should be worthy of its policy.

The Chairman suggested that the use of good type and white space should be considered together, because it was the balance which made a good advertisement. Some advertisements seemed to have a peculiar air of distinction; and this indefinable but very real effect could only be achieved by artists.

Mr. Elson, replying to the discussion, agreed with Mr. Pickering as to the value of some distinctive symbol. The figures cited by Mr. Ardley were a complete justification of the plea for a carefully organized postal campaign. Referring to Mr. Bishop's remarks, the 8-in. double-column advertisement was the standard of the "B.C.G.A." He thought that it was good policy to support parish magazines, quite apart from the revenue secured. He had omitted to mention kinema advertising. The principles of this were much on the same lines as those applying to poster work. The message must be brief. Mr. Oughton's suggestion for a regular advertisement was governed by cost considerations, but would no doubt be applicable to local papers. In the showrooms a regular change of appeal was essential, but this was often a costly item for the small undertakings. It was for this reason that the "B.C.G.A." had incurred the heavy preliminary costs of various lay-outs, the use of which would enable any undertaking to have periodical changes. Circular letters must be produced carefully. Literature paved the way for the salesman, and covered the ground much more effectively than a salesman could hope to do. Circular letters should not be issued in a haphazard manner. Mr. Garward's experience of the benefits accruing from the welcoming of complaints pointed to the advantages of a more general application of the principle.

Gas and Teeth.—Salesmen who desire to know of the important part taken by gas in dental work cannot do better than investigate the contents of No. 133 of "A Thousand-and-One Uses of Gas," issued by the "B.C.G.A." A copy should be placed in the hands of every dental surgeon and others professionally interested in this work.

Midlands Circle.

A most successful Meeting of the Circle was held on April 8, in the Chamber of Commerce, Birmingham—Mr. G. M. Lewis in the chair.

SALE OF TOWN GAS AS AN INDUSTRIAL FUEL.

By H. R. Hems, Industrial Research Laboratories, Birmingham.

I think that insufficient movement is taking place in the gas industry with regard to the application of gas to industrial heating propositions. Much has been accomplished by the few enthusiastic undertakings who have taken up the question seriously, and I believe every one of them has been rewarded far beyond expectations for the efforts they have put forward. What has been accomplished by the few larger concerns can be done—though necessarily by obvious limitations to a minor degree—by the smaller undertakings, particularly those in manufacturing or industrial areas.

What are the possibilities of town gas for industrial use? Let us look for a moment at the achievements of those who have tackled the problem. In America in 1911, only 5 p.ct. of the total gas sold was used for industrial purposes; in 1921, this had risen to 25 p.ct. of the total output. In London, the Gas Light and Coke Company in 1923 supplied 10 p.ct. of the total output to factories and workshops. In Leeds at present the output for industrial purposes approximates 25 p.ct. of the total output; furnace consumptions alone being responsible for over 7 p.ct. In Smethwick, at March, 1910, the industrial consumption (including power) was 10·62 p.ct. of the total consumption; at March, 1919, this had risen to 33·28 p.ct.; at March, 1924, the figure was 41·10 p.ct.; and at December, 1924, the industrial consumption (including power) was 45·77 p.ct. of the total consumption (nine months' working). In Birmingham, at March, 1911, the industrial consumption for furnaces only was 5·06 p.ct. of the total; in March, 1918, it was 22·33 p.ct.; in March, 1924, it was 17·12 p.ct.; and to December, 1924, it was 18·72 p.ct. of the total.

Here are the actual figures of consumption obtained over a period from a standard type of oven furnace installed for the annealing of brass pressings. The furnace is 36 in. deep, 18 in. wide, and 12 in. high (internal working space), and deals with approximately 14 cwt. of work per 8-hour day (including "getting-up" period) for an average gas consumption of 1·81 c.ft. per lb. of work annealed.

		Cents.

,,	Michaelmas ,,	118·4	Furnace installed
,,	Christmas ,,	116·5	
1924.	Lady Day ,,	114·8	
,,	Midsummer ,,	110·3	
,,	Michaelmas ,,	113·6	
,,	Christmas ,,	133·6	
1925.	Lady Day ,,	124·7	

In setting out for new industrial business, we have three main points to consider:

1. The prospective customer—who may, of course, already be a consumer—and his requirements.
2. The appliance manufacturer and his apparatus.
3. The gas undertaking and its service facilities.

With regard to the prospective consumer and his requirements, however you may have received his inquiry, it is necessary to visit his works to ascertain present methods and also to discuss the possibilities of gas fulfilling his requirements satisfactorily and economically. Use every endeavour to gain his confidence, and listen carefully to all that he has to say on the particular process in question. It may appear very simple to replace his existing methods with up-to-date gas apparatus; but remember that your man may have a life experience behind him, and there are many pitfalls in some processes which need watching for.

I think it can be truly said that the majority of gas undertakings owe their industrial loads to the furnace and industrial apparatus manufacturers. This is not as it should be. So far, most of the experimental work has been carried out and the cost borne by them; and I think that gas undertakings will have to do much more of this work in the future. An apparatus manufacturer only has interest in a furnace or similar apparatus up to the point of sale, whereas to the gas undertaking the appliance is going to be a continual source of income so long as it is maintained in good order, as will be seen from the figures already quoted.

Last, but most important, we have to consider ourselves in this question. It is assumed we are prepared to provide a supply of gas of a constant calorific value at a good steady pressure. The rest of the matter is in the hands of the representative of the gas undertaking who has the industrial business in hand. Regarding the man himself, in my opinion he should be a combination of an engineer and a salesman. If this can be obtained in one man, all well and good; but if not, then possibly two separate men, each possessing qualifications in his own branch, may be required. In any case, whoever handles the proposition needs to study his consumer, be capable of dealing with the apparatus manufacturer, and also know his own undertaking and its methods of service in this direction. He must possess common-sense and tact to a very large degree. I know this is necessary in dealing with the domestic consumer; but with the prospective industrial consumer it is even more essential, because all industrial consumptions legitimately obtained to-day are a matter of facts and figures, not fads and fancies.

May I be permitted to outline a scheme to you which I think is elastic enough for application to both small and large undertakings? I suggest that a man possessing some qualifications for the work be appointed to deal with industrial consumptions either entirely, if the possibilities justify it, or partly with other investigational work. He should study the trade of the particular district, and then arrange for a canvass of all the manufacturers with a view to ascertaining what processes are carried out in the works visited, and putting forward the claims of gas as a fuel. This visit should be preceded by a letter enclosing a copy of one of the "Thousand-and-One Uses for Gas" dealing with applications of particular interest to the manufacturer, or one of general interest.

If the premises visited are already partly equipped with gas apparatus, this visit is a good opportunity for inspection of the existing plant and the putting forward of any proposition which may mean increased efficiency and economy for your consumer. It also affords facilities for taking details of this plant with a view to compiling a special record of industrial consumers and apparatus.

Having obtained the interest of the manufacturer, the question of demonstration of the suggested gas apparatus becomes of importance. This is one of considerable difficulty even to the larger undertakings, for it is not possible in a well-equipped industrial demonstration room to show every type of furnace or apparatus. Much, however, can be accomplished with just one or two standard types; and as gas is coming more and more into use as an industrial fuel, it should be possible to arrange exchange visits between gas undertakings for inspection of particular types of apparatus, the "B.C.G.A." being the medium through which an undertaking might ascertain where plant to suit their particular requirements is installed.

After installation of the plant, a periodical visit of inspection should be made by the industrial representative, and if possible necessary repairs carried out by men employed by the gas undertaking. If you can possibly keep the personal visit up, do so by all means—a manufacturer likes to feel that you have his interests at heart.

Muffle Furnaces.

Muffle furnaces are used in the smaller sizes from 6 in. by 4 in. by 3 in. to 30 in. by 18 in. by 12 in. for all kinds of jewellers' work, including the annealing of gold and silver, assaying, and jewellers' enamelling work requiring definite heat control and radiant heat only, without products contact. These furnaces are especially suitable for the heat treatment of delicate carbon-steel tools such as gauges, &c., where freedom from scaling is sought. They are most satisfactorily heated by low-pressure burners (except where quick heating is desired), either in the form of a row of small units supplied from a burner rail and playing centrally along the under part of the fireclay muffle lining, or by one or two units of the ring burner type depending on the size of the furnace.

The following particulars of three standard sizes of muffle furnaces give an idea of gas consumption.

Size of Muffle—	C.Ft. per Hour.
6 in. deep by 4 in. wide by 3 in. high	40
14 ,, ,, ,, 8½ ,, ,, ,, 3½ ,, ,,	100
30 ,, ,, ,, 18 ,, ,, ,, 12 ,, ,,	300

The larger sizes of muffle furnace are now of the recuperative or regenerative types and are used for enamelling small articles in large quantities, such as gas burners, or large iron plates. They are also employed for the heat-treatment of special alloys where very delicate adjustment of temperature and atmosphere is required. One furnace we have installed in Birmingham on this principle, having a muffle 7 ft. by 3 ft. by 18 in., used for gas burner enamelling, and running continuously day and night, has a consumption of about 600 c.ft. per hour, with regular door openings for loading and discharging.

Oven Furnaces.

This type of furnace is more used than any other. In its smaller sizes it takes the place of the old-fashioned hearth for the heating-up of carbon-steel tools, &c., for hardening purposes, and will also deal with small quantities of annealing or case-hardening. Gas-heated oven furnaces range in standard sizes from 12 in. deep by 9 in. wide by 6 in. high up to 36 in. by 24 in. by 12 in. (internal working space). They are most satisfactorily heated by low-pressure gas, and there are three or four very good designs on the market eminently suitable for heat-treatment operations requiring temperatures up to 950° or 1000° C.

The following are details of one or two standard sizes of oven furnaces:

Size.	Maximum Consumption.	Maintaining Consumption for 800° C.
	C.Ft. per Hour.	C.Ft. per Hour.
12 in. deep by 9 in. wide by 9 in. high	180	100 to 150
24 in. deep by 18 in. wide by 12 in. high	300	200 to 250
36 in. by 24 in. by 12 in. or 15 in. high	500	300 to 400

Great care should be exercised in advising a consumer to instal the larger sizes

of power furnace. They are satisfactory where short period heating (8-hour working day) is desired, or quick reduction of temperature at the conclusion of an operation is required. If the proposition is a long-period or continuous-heating one, consideration must be given to furnaces designed with continuous counter-current recuperators of either firebrick or metal, or the regenerative type.

Should temperatures higher than 1000° C. be required, recuperative or regenerative furnaces must be used for either muffles or ovens.

Forging Furnaces.

Into this category would be placed all patterns of furnace in which a flame is playing directly into the working hearth, and is in contact with the work to be heated. These furnaces are usually heated with a gas and air blast burner supplied with gas at ordinary town pressure and air at from ½ to 2 lbs. per sq. in., as this method provides a rapidly-obtained high temperature in the working chamber, and a high rate of transference of heat to the work to be treated.

The work would include that of high-speed steel hardening requiring a temperature of about 1260° C., normally in a comparatively small space. This form of furnace is usually made with a preheating chamber. A furnace having a chamber 6 in. by 6 in. by 6 in. would be heated to a temperature of 1300° C. in 20 to 30 minutes with a gas consumption of approximately 200 c.ft. per hour; a blower capable of dealing with about 1500 c.ft. of air per hour being required to supply the air.

Small furnaces of this design are also employed for the heating of small brass billets for hot stamping work. Bigger furnaces are used for the treatment of large sizes of high-speed tools, and also for the general forging operations of steel blanks into various shapes, and the production of nuts and bolts. In the manufacture of the latter, the following figures may be of interest. Over a two days' test, a gas consumption of 15,000 c.ft. per ton of nuts and bolts was found to be required, which, with gas at 2s. 4d. per 1000 c.ft. *less* 5 p.ct. (Birmingham price) would amount to £1 13s. 3d. per ton.

Melting Furnaces.

The next big field for the utilization of town gas as a fuel lies in the development of the melting furnace. A great deal of useful work was accomplished a few years ago in this direction; many firms and several gas undertakings obtaining some very fine results. It is a pity that, since the war, gas prices have so much increased that at present we cannot obtain any consumptions for ordinary brass-casting or similar furnaces. With aluminium melting, the position is brighter, especially since the use of the cast-iron pot for remelting came into general use. Very little consumption for this process was lost even during the period of highest price. Tin, lead, and soft metals generally are most successfully melted with gas; and costs compare favourably with other forms of fuel. The following figures will give you an idea of the costs of melting various metals:

Brass, 4 c.ft. per lb. (in small quantities)	Approx:	9,000 c.ft. per ton
Gunmetal, &c., 5 c.ft. per lb.	,,	11,000 ,, ,,
Aluminium	,,	8,000 to 9,000 ,, ,,

For brass melting consumptions to be regained and retained, gas needs to be sold at about 1s. 6d. per 1000 c.ft.

I wish to thank the Birmingham Gas Committee and Dr. C. M. Walter, Engineer-in-Charge of the Industrial Research Laboratories, for permission to read this paper, and for the use of information obtained in the course of my official duties.

Discussion.

Mr. G. M. Lewis believed that in every town there was some field for industrial heating to which gas could be applied. He instanced such apparatus as glue-pot heaters, soldering-iron stoves, blowpipes, and hot water for sports pavilions, as some of the processes which would almost invariably be in existence within the area of every undertaking. Mr. Hems' figures showed a great extension in the use of gas for heating within recent years, but he felt sure that a vast consumption was as yet untouched. He agreed that the manufacturers of apparatus had done a great deal to assist in the development of gas sales, but felt that it was the duty of the gas undertakings to advise consumers, push the sale of the right appliances, and fix and maintain them.

Dr. C. M. Walter (Engineer-in-Charge, Industrial Research Laboratories) emphasized what Mr. Hems had said with regard to service. He considered that with industrial consumption this was of paramount importance. Speaking of furnace repairs, he said that all furnaces were subject to wear, owing to the high temperatures employed; and replacements of parts were necessary. The manufacturers of furnaces catered well for these replacements, but the difficulty was that the jobs were usually wanted very quickly, and he considered it necessary to have a skilled man always available to carry them out. Every opportunity for repair or adjustment was an opportunity for possible improvement, such as alteration in refractory material, &c.; and thus the user was kept satisfied. Dr. Walter agreed that there were opportunities for an industrial load in every undertaking. A complete canvass would be sure to discover some consumers; and this business, once started, would grow when the value and efficiency of gas heating were more fully realized.

Mr. G. Burden (Redditch) congratulated Mr. Hems on his paper. He had told them not only how to set about getting business, but what to do when it was obtained. At Redditch they had recently sent a letter to about forty factories asking for opportunity for examination and maintenance of their apparatus. The results were proving most satisfactory, and gave an opportunity for getting into personal contact with the consumers. Small undertakings found themselves in difficulty because they were unable to employ a man who could specialize exclusively in this class of work. He suggested that some sort of advisory and consultant board in the Midlands would be most useful to the smaller undertakings. A demonstration room was almost a necessity if new business was to be obtained.

Mr. J. A. Davis (West Bromwich) raised the question of competition with producer gas for annealing purposes.

Mr. S. W. Simmons (Dudley) stressed the necessity of first gaining the confidence of the consumers. All figures given of costs and consumptions should be conservative and capable of attainment under ordinary working conditions. He advocated the sending of a letter before a call was made, but thought that letters, circulars, &c., were of very little use unless followed-up by a personal call. He spoke of the use of gas for metalizing processes in Dudley.

Mr. J. Pemberton (Stoke-on-Trent) said that in the Potteries their need was for a satisfactory method of heating large furnaces of a size approximating to (say) 6 ft. by 10 ft. by 4 ft. Experiments made on small furnaces were of little use unless the results could be translated into terms of large furnace working. He believed that these large furnaces could be successfully designed and economically worked; but the trouble was the high first cost. Manufacturers were disinclined to put down the large amount of money necessary on a process in which gas had not been previously used, and which they looked upon as somewhat in the light of an experiment.

Mr. Hems, replying to the discussion, mentioned the improvement that had been made in the construction of the soldering-iron stove. He thought it possible to deal with the large furnace work mentioned by Mr. Pemberton. Unsuitable apparatus was the bugbear of the whole furnace business, and caused endless trouble.

Mr. T. B. Armitage (Cheltenham), in proposing a vote of thanks to Mr. Hems, stressed the necessity for co-operation between the smaller towns in dealing with industrial work.

Mr. Pemberton, seconding, deplored the small number of students in the gas industry, and thought that any interest that could be aroused among the children and teaching authorities would be of great value.

At the close of the meeting many of the members visited the Gas Department Stand at the National Trades Exhibition at Bingley Hall.

Scottish Circle.

A meeting of the Circle was held in Edinburgh, on Wednesday, April 8. The President (Mr. Jamieson, Assistant Gas Engineer, Edinburgh) was in the chair.

MAINTENANCE OF GAS APPLIANCES.

By W. S. Anderson, of Perth.

It is impossible to get a department in which there will not be complaints from the consumer as to consumption of gas, want of supply, or faulty appliances; but, if these complaints are attended to with promptitude and courtesy, it may be—as has frequently happened in our department—that, instead of doing harm, it will actually help.

One of the most valuable assets we have is a bond of sympathy between the consumer and the gas department—in fact, the consumer is the best publicity agent we have, especially in a provincial town like Perth. The aim of the salesman should always be to foster that spirit by tactful dealing with the consumers. Such a spirit has existed in Perth for many years. Of course, the gas department have been very generous in respect of terms of hire of apparatus. We supply all domestic sizes of cookers and fires at the small hire of 2s. per annum, fixing free up to 30 ft. of pipe from the meter. Radiators, geysers, water heaters, and wash boilers are hired at 4s. per annum; the consumer paying for the water connection only. Smaller articles—viz., hotplates, rings, and irons are given at 1s. per annum. We do a considerable business in hire-purchase of such articles as are outside the usual hire rates—viz., new cookers, circulators, and any special appliances. These we give in fifteen payments over a period of five years. We have in Perth 11,536 consumers, and nearly 15,000 articles out on hire (cookers 5200, fires 2350, water heaters, geysers, and boilers 700, small appliances—hotplates, irons, and rings—7000).

Our responsibility ought not to cease with the supplying and fitting-up of appliances, even though these are fitted by our fitters, and not by outside plumbers, as is the case in many towns. Without proper instructions the appliance may not give the results it ought to, and may be blamed unjustly. Therefore maintenance is a necessity. This is specially applicable to gas fires. We carry out periodical inspections of all appliances; and should we discover any cooker or any other apparatus which we consider in need of an overhaul, we bring it into our workshops, have it attended to, and return it to the consumer almost as good as new. In the interval we loan a hot-

plate. In connection with the aforementioned survey, inspection cards have been prepared showing all the appliances that each consumer has in use.

In the matter of showrooms, we have been a little unfortunate in Perth, owing to the situation being in a back street where there is little regular traffic. A good showroom in a central position would be a great asset to us in Perth. However, we are doing our best with the material in our hands. Pendants, brackets, glassware, and all classes of shades, &c., in addition to cooking and heating appliances, are displayed. The customers are not pressed to buy; but should they desire anything, we pass the order through their own plumber or ironmonger, as some years ago an arrangement was made with the gasfitting trade to allow them to use our showrooms. This has proved fairly satisfactory; but as many of the ironmongers have still continued selling cheap and shoddy burners, &c., we decided to sell direct to the customers, if desired. At the beginning of January we appointed two new maintenance inspectors, who are doing door-to-door work, cleaning and overhauling burners, &c., and only charging for the material used. In re-introducing the maintenance inspection, we are only going back to work we did many years ago in the days of the flat-flame burner.

To my mind there is not nearly enough attention paid to the lighting of houses and schoolrooms, especially when we hear so much to-day from our medical men of the injury done to the eyesight of children through bad lighting. An expert, writing on this subject some years ago, said: "Good light is of vital importance to the adult in his daily occupation, but still more so to the child at school or in the nursery. It is therefore the duty of parents to see that any reading or fine work undertaken by the children during the evening is not done in gloomy, ill-lighted corners of the room. While reading at home is optional, study at school is compulsory. How much greater, therefore, is the responsibility of school authorities to see that the school rooms are well lighted. Medical authorities tell us that a progressive deterioration in eyesight occurs during school life. We can readily understand why this should be the case, for a child working by insufficient light instinctively tries to bring the book nearer to his eyes, or bends so as to bring his eyes nearer the work. This constant close vision is believed to be one of the main causes of short-sightedness. Moreover, the habit of assuming a stooping attitude is bad for the child. Children are sometimes blamed for such habits; but are we sure that the blame should not rest on their elders for allowing bad conditions of illumination to exist, and so paving the way for the stooping habit?"

It is of utmost importance that we of the gas departments do our part to prevent the charge being made against us. We certainly need an A.1. nation, if we are to hold our own in the world's struggle. This is not possible with stooping, short-sighted children. Homes must be well lighted; and gas alone can do it. Some time ago the "Lancet" had the following remarks: "For some not very clear reason the light of the electric lamp seems to be wearying, taxing the eyes; and a good many people complain that reading by electric light gives rise to headache." The experience of one authority had proved that electric light did a large amount of serious harm to the eyes.

We have recently re-fitted two schools; and the results have been very satisfactory. During this season we re-fitted a large church, using superheated burners. Those interested have expressed themselves as delighted with the result. We also installed semi-indirect fittings, with distance control, in a hall. Though estimates had been lodged for electricity, the authorities decided to make no change. I believe that much could be done by pushing distance lighting for houses, especially when maintenance is in force. I have had a pneumatic switch in use in my own house for fifteen years, with good results—in fact, there has been no trouble whatever. In one of the rooms I use two switches, one at the door and the other at the bed. The pneumatic switch is specially useful in lobbies and halls; as it saves a light being on all night when it may only be required two or three times.

The doctors in Perth favour gas fires; and nearly all have them in their consulting rooms and throughout their houses. We are also on good terms with all the architects in the city. In the housing schemes cookers and wash boilers are being installed in all the houses; and in many cases fires are being fitted as well. All the Institutions in the city are heavy consumers of gas, especially the Royal Infirmary, where most of the cooking is done by gas. At present we have an inquiry on hand to instal a large cooking range to substitute the present coal range. When this is carried through, all the cooking will be by gas. They have gas hotplates in all the ward-kitchens, and all the sisters' rooms have gas fires. About a year ago a new outpatient department was built. This is fitted with gas; a circulator being installed for the water supply. Most of the hotels and restaurants use gas for cooking, and all the smaller halls and many of the churches in the city are heated by gas-steam radiators.

During the last two years we have gone over nearly the whole of the city, and renewed the services street by street, employing five squads of men to do the work. Already we are reaping the benefit in the reduction of complaints.

Discussion.

Mr. SIMPSON (Greenock) said he thought Perth had an excellent record in regard to the number of articles on hire in proportion to the number of consumers. The gas department should have complete charge of all the internal fittings. Attention should be paid to the lighting of schools and churches. In Greenock during the past year they had fitted over 800 new boilers on the maintenance system. He felt it was really worth while increasing the staff of maintenance men.

Mr. N. S. SMITH (Greenock) said a well-organized maintenance system was the undertaking's best method of building up goodwill. A maintenance inspector should be something more than an ordinary fitter. He should be a good salesman. A "handy" man could be trained in a few weeks in the art of cleaning and adjusting burners, cookers, fires, &c., but he might never become a maintenance inspector in the full sense of the word, because he was not temperamentally suited for the job. The duties of the maintenance man should be to instruct the consumer how to get the best use out of the appliances, and how to keep them in order—one demonstration in a hou should be sufficient. He should also do a minor adjustments, take a census of all a pliances on the premises, see that the servi meter and fittings were adequate, and e deavour, in a judicious manner, to introdu new business.

Mr. GRAHAM (Kilmarnock) asked if the was any limit to the value of the article su plied free.

Mr. ANDERSON replied there was not, if th article was considered necessary. Nor wa there any guarantee needed of consumption.

Mr. GRAHAM said he should be disincline to hire on those conditions. He would put limit on the value of the appliances, or find the consumption was going to repay them He thought it was a good thing to put th maintenance cost on the price of gas.

Mr. GAVIN (Galashiels) remarked that on of the most valuable assets was that bond sympathy between the consumer and the ga department. It was desirable to have a understanding with the local Press.

Mr. DOW (Galashiels) thought that plumbe regarded gas fitting as a side issue. N plumber should be allowed to put in any ga fitting until he had passed a qualifying test- when he knew what size of pipe would carr a certain quantity of gas for a given purpos The price of gas appliances to-day did n warrant the small hire charged at Perth. would be twenty years before the capital re presented by these appliances was repaid, an by that time they would be worn out. Galashiels they were very fortunate in havin a showroom in the main street. They di good business by advertising in the loc Press and by keeping their showroom lighte till eleven o'clock. Gas fires ought to b pushed only in conjunction with industrial ap pliances, to avoid peak loads.

Mr. TAIT (Edinburgh) said that geyser were put out on hire, but the householder ha to pay for the fitting.

Mr. CHISHOLM (Leith) said that in Edin burgh they made periodic inspection of ga fires only. They made a charge for exchang ing cookers.

Mr. DARLING (Cowdenbeath) spoke i favour of a free maintenance scheme. Th advertisement alone was worth it. Windo displays brought very good business. At Cow denbeath they kept the lights burning ti eleven o'clock.

Mr. G. KEILLOR (Greenock) suggested tha gas fires in hospitals should be inspected an put in order every month or six weeks, be cause, when the beds were made, there wa always a lot of fluff flying about. It was thei business as salesmen to become friendly wit plumbers, and teach them what was wante in the way of service and piping.

Mr. DUFF (Edinburgh) said the questio of maintenance was becoming one of the mos important in the gas industry. He would lik to have a copy of various systems of mainte nance work exchanged between towns of equa size.

Mr. WILSON (Edinburgh) maintained that unless they made periodic inspection, the could not get proper efficiency. In Edinburgh many houses were being divided, and they ha no difficulty in getting architects and plumber to instal pipes of the proper size.

The PRESIDENT remarked that skilled me only should be put on maintenance work.

Gas House-Heating Contest.

A New England Scheme.

The Gas Sales Association of New England (with the help of friends of the industry who are anxious that it should secure the maximum business benefits from gas heating) are offering a series of prizes in connection with what should prove highly valuable competitions.

There is to be a first prize of $100 and a second prize of $75 for New England gas company employees presenting the best reports for use by others as sales helps during the summer and autumn in obtaining new heating installations. This contest closes on May 1.

Then first and second prizes of $100 and $75 respectively are offered for the best window displays of heating equipment made between now and October. For the purpose of deciding the competition, photographs with descriptions not exceeding 500 words are to be submitted. There is no limit to the number of photographs or displays that may be submitte by an individual company. The prize will be awarded to the commercial depart ments of the winning undertakings, to b distributed among their salesmen.

Two prizes of $50 each are offered fo the sale of the most heating equipmen during 1925—one to be awarded to a com pany with a heating rate of less than $ per 1000 c.ft., and the second to a com pany with a rate of $1 or over. The number of installations per 1000 meter and the total sales value of the installa tions made are both to be taken int account in making the awards. The sale value will include gas piping, flue piping and thermostats, where these are em braced in a lump sum price of equipment sold ready for use. Among the apparatus to be considered as heating equipment ar steam, vapour, and hot water boilers, hot air furnaces, radiators, and gas fires, pro vided they are permanently installed wit rigid connections. In this case, also, th prizes will be awarded to commercial de partments.

West Riding of Yorkshire Circle.

A Meeting of this Circle was held at he Town Hall, Ossett, on April 8, when n interesting paper on the importance of he gas salesman was read by Mr. A. E. Iottram, Engineer and General Manager o the Ossett Corporation Gas Depart- ient. There was a very good attendance f members from all parts of the Circle's rea. Mr. S. H. Packer (Bradford), the 'resident, presided over the meeting.

Prior to the business proceedings the nembers were entertained to tea by the Ossett Gas Committee, and the gathering ncluded the Mayor (Mr. D. Ellis) and the Chairman of the Gas Committee (Mr.). B. Broadhead).

Mr. Broadhead, on behalf of the Gas Committee, offered a brief but warm wel- ome to the members of the Circle, and ex- ressed the hope that their meeting would e successful and beneficial.

The Mayor, offering a welcome on be- alf of the Town Council, said he was atisfied that there was a great future be- ore the gas industry. He noticed from nnual reports that in most gas under- akings the consumption was steadily in- reasing; and he wished the gas industry nd those engaged in it all prosperity.

The Chairman thanked the Mayor and Mr. Broadhead for their welcome. The olicy of the Circle this year was to stir up he enthusiasm of the gas salesmen in the maller undertakings; and the attendance t the present meeting certainly spoke well or the interest of the salesmen of the Vest Riding. He moved the hearty thanks f the gathering to the Mayor and Cor- oration, the Gas Committee, and Mr. Iottram for their hospitality.

Mr. C. Watson (York) seconded; and he motion was carried unanimously.

Between the conclusion of tea and the pening of the business meeting, the nembers inspected the showrooms of the Ossett Gas Department.

Mr. Packer presided over the subsequent neeting, and remarked that it had been is pleasure to welcome many gas ngineers to their meetings. He had great leasure in introducing Mr. Mottram, who ad a keen sympathy with the objects of he Circle.

THE IMPORTANT POSITION A GAS SALESMAN HOLDS TO-DAY.

By Arnold E. Mottram, Engineer and General Manager, Ossett Corporation Gas Department.

Gas engineers have for years concen- rated to a large extent upon improving he gas-works; vast strides have been nade—retort houses are practically per- ect, and capable of turning out an un- imited quantity of gas; mains have been un throughout the country; distribution as been well studied, and every house has service available. The manufacturers of as appliances have done their part mag- ificently. Think of the efficiency of the as engine of to-day, the gas-heated steam oiler, the cooker, the wash boiler, and the re. We have the gas, we distribute it ell; and we have the appliances for con- uming it. We now desire to link-up the onsumer and the appliances. This, I take t, is your work.

Gas is a household word, a household ecessity, with a future bright with pos- ibilities. Have you all got the qualifica- ions for the positions you hold? The first ne that comes to my mind is that you hould have the happy knack of winning he confidence and goodwill of the cus- omer. You should be alert without being 'cheeky;" you should be bright and speak learly and with confidence. For this it vill be necessary for you to have a good nowledge of the appliances you are sell- ng. This does not by any means com- plete your education. Do you find your work interesting? If so, you are bound to get on. If, on the other hand, you are simply passing your time away in the showroom, until something better turns up, I am afraid you are doing more harm than good. You want to know when not to sell an article, as well as when to sell it. If you are satisfied the appliance is wrong for the work it has to do, you must refuse the business. You will have lost one sale, but will have prevented a bad advertise- ment which would probably have lost a score of sales.

The sale of gas for power is good busi- ness for both the buyer and the seller. In many small workshops a steam boiler is put in because a small quantity of steam is wanted. A gas engine might be put in, and the waste heat from the exhaust used to generate the steam. Waste-heat boilers can now be obtained for this purpose. The gas cooker of to-day is an ornament to any kitchen, as well as being far away the most serviceable article for the purpose. The gas boiler has done away with the dirty, nasty set-pot, which in the olden days drove many a poor washerwoman to drink. Gas fires have been perfected, and are suit- able for all requirements. They are very important labour-savers. A gas fire in a bedroom, lighted for twenty minutes be- fore you retire, will ward-off many an ill- ness.

Incandescent gas light is the cheapest illuminant, and certainly best for the eyes. Its ventilating qualities give it an advan- tage over other methods of lighting. When one thinks of the thousand-and-one gas appliances which the gas salesman must know all about, one realizes that his qualifications should cover a wide range. You have great scope for your energy. Endless business is waiting for you.

I saw in the paper the other day an argu- ment as to whether it was the common practice for the husband to get up first in the morning, and do the dirty work of lighting the fire, or whether it was usual for the wife to do so. I should imagine that it must be usual for the wives to light the fires, because I think that if a man did it for two or three mornings, he would use up all the bad language he knew, and would then call at the gas showroom and order a gas fire. Do you not think that a guessing competition, as to who lights the fire, would be a good advertisement for gas, and bring home forcibly to the one who does light it the waste of time and temper spent on a coal fire?

Think of the large number of consumers who never come near the showroom. They must need gas appliances. Surely you are not going to lose their custom? How do you propose to secure it? If they do not come to you, you will have to go to them. If you were to take a lorry load of samples with you, it is certain you would book a lot of orders.

The smoke nuisance is a topic widely dis- cussed. You have a grand opening here, for you have the means at hand for greatly reducing this bugbear.

I have no fault to find with electricity in its proper place. It has its uses; but I think it derives some of its light from blushing at some of the things claimed for it. I will just mention one point, which puts it in its proper place in comparison with gas. Mr. D. Milne Watson, the Governor of the Gas Light and Coke Com- many, recently stated that his Company alone produce in a year as much energy for light, heat, and power as is produced in the form of electricity by the whole of the electrical undertakings in Great Britain. He also stated that his Company sent out last year 183 million therms, for which the consumers paid £6,000,000. To replace this gas by electricity, at the same total cost to the consumers, the electricity would have to be sold at ¼d. per unit. Last year's average price of electricity for all purposes, totalling the whole of the country, was 2d. per unit, so you see how much cheaper gas is than electricity.

We hear that the Government are likely to give the electrical industry £50,000,000. I am sorry for the receivers—they must be in a hopeless state. The givers will naturally have some control. We have seen in the past the dire result of Govern- ment control of industry; and if the pre- sent electricity works, which are not yet paid for, are to be scrapped to make way for more costly ones, the first £50,000,000 will not go far. This money will have to be paid back with interest by somebody.

It looks as if the electricity consumers will have to pay twice over for what they use—once through their electricity bills, and a second time through their rates and taxes. A sum of 50 millions is equal to an increase in income-tax of 1s. 6d. in the pound for twelve months. In this way people are told they are going to have cheap electricity.

Electricity works are very wasteful users of coal. Only 10 p.ct. of the coal used in the boilers is sent out of the works in the form of electricity; 90 p.ct. goes up the chimney and is wasted on the works. The new super electricity works which are to be built are to waste 80 p.ct. of the coal. These are their own figures; so you may be sure they are the best they can hope for. On the other hand, gas-works send out in the form of gas and residuals 75 p.ct. of the coal they carbonize, and only waste 25 p.ct. in the process of manufacture.

We at present charge 4s. per 1000 c.ft. for gas for domestic lighting. Electricity for the same purpose is 6d. per unit. Taking the best ordinary inverted gas burner, and the best electric lamp, the householder of this district who has adopted electric light is paying for his elec- tricity equal to 8s. per 1000 c.ft. of gas, light for light. Not only this; he is pay- ing in his 6d. a unit a large part of the bills of the large electricity consumers, who are getting current for about 1d. per unit.

I do not think we need waste much time in considering the heating of the house by electricity. The cost is prohibitive, and from a health point of view electric heating is bad. A gas fire in the grate assists ven- tilation; but the electricians' method is to place electric heaters about the room, stab the people in the back with a ray of heat, and at the same time poison them with their own breath, for it is impracticable to place a fan in every room.

In conclusion, I do not think your pre- sent value is permanent. You have such a wide scope before you that you should rise to become the most important branch of the gas industry.

Discussion.

The Chairman said they were all deeply in- debted to Mr. Mottram for a helpful and en- couraging paper.

Mr. C. Watson (York) remarked that the gas salesman was different from the majority of salesmen of other businesses. In the latter case the salesman sold what the customer asked for, and as much more as he could get rid of. The gas salesman had to sell what the customer really needed; and this did not necessarily mean the exact article asked for. The gas salesman must understand what his various appliances would do and would not do, and he must ascertain the requirements of the customer, and try to sell the appliance which would give the best results in service. Sometimes it needed a great deal of tact to persuade a customer that what was really wanted was something different from that re- quested. The gas salesman had to study human nature closely, and learn to understand the peculiarities of the customer. Mr. Watson said he believed in encouraging people to bring their complaints, so that they could be dealt with and remedied. Very often, by so doing, obsolete apparatus could be replaced. In any case, the salesman got into closer touch with the customers, and could introduce new and better types of apparatus, and could

take measures to ensure a better service. There was a good deal of shoddy gas apparatus being sold; and it would pay the gas departments to buy up at a low price old apparatus of which consumers were complaining. There was an old question—whether a gas salesman was born or made. He thought the salesman was born, but had to be educated to his particular business. When customers found that the department were anxious to give the best possible service, more business resulted. The gas salesman's work involved continuous interest in consumers' needs. Lighting was still a factor which counted for a great deal. In the matter of obtaining new business, Mr. Watson suggested that gas inspectors should get into touch with architects, builders, clerks of works, prospective occupiers of new property, and not wait for the possible customer to come to the showrooms.

Mr. F. LODGE (Wakefield) said that the importance of the position of the gas salesman had only come to be recognized in recent years. He suggested that the increased business was due in large measure to the opening of showrooms. Gas appliances to-day were very efficient; and if people would come to the showrooms they could be shown something which would interest them. If they would not come to the showrooms, then the salesmen must go to the people. This was being done more and more every day. Mr. Lodge suggested that it was a great advantage to have things so arranged that at the place where people paid their gas accounts there should be facilities for them to see gas appliances and make inquiries. Everybody in the gas department was a potential salesman, and he thought the accounts department should foster sales. Up-to-date maintenance schemes and appliances, and steady education of consumers to keep their appliances clean, would retain a great deal of the gas lighting load.

Mr. L. DENHAM (Halifax) remarked that an important point mentioned by Mr. Mottram was that of gaining and keeping the confidence of the consumer. It was a point which could not be stressed too strongly. Another important matter was that of comparison by salesmen of electricity and gas. He did not suggest that all mention of electricity should be prohibited, but he saw no reason why gas salesmen should be constantly advertising electricity and reminding people of electricity by talking of it in comparison with gas. When selling gas appliances, they should talk gas appliances.

Mr. E. BAILEY (Cleckheaton) pointed to the necessity for having intelligent and capable gasfitters. He was strongly in favour of an educational scheme for fitters in each gas undertaking. Men who were sent into the consumers' houses to do work must be a credit to the undertaking. Supply pipes, &c., should be as neat as possible. Gas departments did not always allow sufficient time for this. It paid to give tuition to fitters, even if the department employed only half-a-dozen or so. All appliances should be inspected (say) twice or three times a year, by someone connected with the gas undertaking.

Mr. J. D. LUPTON (Otley) thought Mr. Mottram was to be congratulated on putting forward very encouraging figures as to the comparative costs of gas and electricity. They were figures which ought to be remembered.

Mr. D. PARSON (Huddersfield) said it might truly be suggested that up to some ten or fifteen years ago the majority of gas engineers had a general impression that all they had to do was to produce cheap gas. Fortunately the bulk of people in the industry to-day realized that something more was necessary in the way of salesmanship. There was still a need for more attention to the installation of the best appliances. The salesman should lose a sale rather than let his department in for something which could not be satisfactory, and which would in all probability eventually result in the loss of a consumer.

Mr. E. STEMBRIDGE (York) said that the salesman might claim much for his apparatus; but if it was not well fitted, it would not give satisfactory service. Periodical inspection was excellent; but in many cases it was not practicable, and the most important thing was that the apparatus should be well fitted.

Mr. A. B. HORSFIELD (Leeds) mentioned that in Leeds they had a scheme under which all fitters attended a course of demonstration and training under the inspectors. The electricity people seemed to do well by their specially favourable system of charging, on a basis of rateable value, for domestic users. It was a method which made electricity compare fairly favourably with gas; and he thought it might be well if gas charges could be put on a similar basis, especially for cooking.

Mr. J. W. CARLTON (Shipley), speaking of obtaining the confidence of the consumer, said that the salesman should not be afraid, if necessary, to tell a customer candidly what an appliance could not do. The fitting should be such that it was a standing advertisement.

Mr. E. ADAMSON (York) agreed that it did good to get to know of complaints. At York they had a staff of men looking for complaints, and they were constantly in touch with the consumers. In regard to fitters, every undertaking could eradicate poor fitters by the simple expedient of training their own apprentices. This was what they did at York. They paid apprentices a decent wage, in order to attract a good class of youth into the industry. Their chief inspector gave weekly classes in theory and practice. The gas salesman might be born or he might be made; but he must be educated, and he must be an opportunist. One of the greatest essentials in the effort to gain public confidence was a consistent quality of gas.

Mr. H. RHODES (Bradford) hardly understood how the salesman could, as Mr. Denham had suggested, avoid mentioning electricity, having in mind the fact that the public would constantly be talking about it to the salesman. The rateable value basis of charging for domestic electricity was in operation in Bradford; but there it did not come anywhere near equalling the low price of gas for cooking, though for lighting in some instances it might run it fairly close. He thought it was only in houses where a great amount of electricity was used for lighting and heating that the cost per unit was brought down to something like the level of gas lighting. In general, with gas at 3s. 9d. per 1000 c.ft., it was cheaper, light for light, than electricity at 3d. per unit. For heating, cooking, &c., gas men had nothing to fear. Many people, of course, went in for electricity merely because it was so easy to switch on and off; and he thought gas departments ought to push the gas switch. They should emphasize the ventilation value of gas lighting. In a good many chapels which he knew in Bradford gas lighting was retained because of the ventilating value.

Mr. H. ROBINSON (Ossett) spoke as a meter inspector. It was the meter inspectors who got into the consumer's houses. They were on the spot; and if they could not effect a big sale themselves, they were in a position to introduce the consumer to the sales department and the showroom. He believed that in many cases they were in a position to arrange a definite sale on their own.

Miss ILLINGWORTH (Ossett) said that in Ossett they were developing the sales side very materially, and were doing a lot more business than formerly. They were developing very successfully the hire-purchase system, especially in cookers. It was largely a working-class district, and both in cookers and gas fires this method of sale was very advantageous.

Mr. R. FAWCETT (Ossett) agreed with Mr. Robinson that the meter inspector could be a useful salesman, because he was so closely in touch with the public. He usually heard of the complaints, and could draw attention to better appliances. If they would take notes of complaints and remarks by consumers, the meter inspectors could do a great deal of good to the industry. He thought the part of the meter man in selling was a subject on which a valuable paper might be given to the Circle.

Mr. H. WILDE, Hon. Secretary (Bradford), endorsed what had been said as to the importance of selling the right article for the right place. Mr. Mottram had touched a little on the public health aspect of gas versus electricity. The gas industry could claim that it did much for public health. Many public officials did not realize the big weight of expert opinion of medical men, professors, sanitary authorities, and others as to what an aid gas could be, not only in eliminating the smoke evil, but also as a ventilating agent. Experts had proved conclusively that a room lighted by gas was much healthier than one lighted by electricity. Mr. Mottram had spoken of general co-operation and increasing business. Undoubtedly the best way to increase business was to get the co-operation of everybody who could influence the sale of gas and gas appliances in any way—builders, architects, &c., and, not least, all branches of employees in the industry itself. Mr. Wilde fully agreed that the outside man could be a great influence.

Mr. C. E. GARSIDE (Otley) said that in many instances the industry was apt to pay too little attention to the lighting business.

Mr. ROBINSON (Ossett) suggested that [illegible] would pay gas undertakings to sell gas [illegible] cheaper prices for gas engines.

Mr. PARSON remarked that the privat[illegible] plumber often did a great deal of shoddy work. He knew of a little chapel, for instance, wher[illegible] to lights and a water boiler were all fitted b[illegible] a plumber to a single ½-in. pipe.

Mr. WATSON mentioned that little had bee[illegible] said in the discussion about that important bu[illegible] silent salesman the attractive showroom. H[illegible] suggested that at the earliest opportunity [illegible] would be well for the Ossett Gas Departmen[illegible] to move its showrooms from the present posi[illegible] tion to a better one.

Mr. BROADHEAD congratulated the member[illegible] on their spirited and valuable discussion an[illegible] on the serious interest they obviously took i[illegible] their work in the industry.

The CHAIRMAN said Mr. Mottram's pape[illegible] had given rise to one of the best discussion[illegible] the Circle had ever had. Mr. Mottram's re[illegible] marks had shown the deep interest which he[illegible] as an engineer, took in the advancement o[illegible] salesmanship. If they could get to the tim[illegible] when every gas engineer would stand up an[illegible] give the correct status to salesmen, as Mr[illegible] Mottram had done, then the millennium woul[illegible] have arrived for them. Mr. Mottram had bee[illegible] at pains to show how wide and deep the quali[illegible] fications of the salesman could go. He ha[illegible] been impressed by Mr. Mottram's suggestio[illegible] as to taking round a lorry, and showing ap[illegible] pliances to consumers who would not or coul[illegible] not go to the showrooms. It was a new ide[illegible] and was probably capable of important develop[illegible] ment. He was glad some of the meter inspec[illegible] tors had spoken of the important service the[illegible] could render in preparing the way for sales[illegible] He wondered whether the industry used a[illegible] much as it might do the great weapon of wid[illegible] publicity for gas in tackling the great smok[illegible] problem. Many of them were in a position t[illegible] dwell on this subject not only in the showroom[illegible] but at lectures and discussions at gatherings en[illegible] tirely outside the industry. Some of them di[illegible] some platform work in connection wit[illegible] churches, Sunday schools, and various socie[illegible] ties; and he thought they had in their hands[illegible] a valuable means of publicity for gas as a[illegible] eliminator of smoke.

Mr. MOTTRAM, replying to the various[illegible] points raised in the discussion, said he en[illegible] tirely agreed that it was good to hear com[illegible] plaints. It was important that people who ha[illegible] anything wrong should let the gas undertaking[illegible] know of it. It was bad to have people saying[illegible] nothing to the undertaking, but doing a lot o[illegible] grumbling among their friends. There wa[illegible] certainly a lot of poor appliances which ought[illegible] to be smashed-up, especially the kind of good[illegible] sold on Saturday night market stalls. He[illegible] agreed as to the importance of getting into[illegible] early touch with people concerned in new[illegible] buildings. The industry did a great deal in[illegible] that direction already. He agreed with Mr[illegible] Watson's criticism of the showroom at Ossett[illegible] In fact, when he first came to Ossett he had[illegible] no idea the showroom was in such a situation[illegible] and he hoped it would not be long before they[illegible] could get a good premises in a main shopping[illegible] street. He agreed also that it was desirable[illegible] to have appliances on view at the place where[illegible] people came to pay their accounts. As to Mr[illegible] Denham's observations on salesmen speaking[illegible] of electricity, he was afraid they could not help[illegible] but attack the electricity claims sometimes, in[illegible] view of the strange things the electric people[illegible] claimed. It was essential that the public[illegible] should be told occasionally that not everything[illegible] they heard about electricity was strictly cor[illegible] rect. He had been very much impressed by[illegible] Mr. Bailey's remarks on fitters, and agreed[illegible] with his suggestion as to training, though he[illegible] fancied he must have had in mind a good deal[illegible] of the work of private plumbers. He entirely[illegible] agreed that appliances should be inspected[illegible] periodically, and kept in proper order. He[illegible] agreed also with Mr. Parson in the suggestion[illegible] that the salesman should refuse to sell what[illegible] was obviously the wrong appliance. He fully[illegible] agreed with Mr. Horsfield as to classes for[illegible] fitters and the training of apprentices, but of[illegible] course a big undertaking like Leeds could do[illegible] some things which were hardly practicable to[illegible] the same extent in smaller undertakings. The[illegible] men at Leeds, who had such splendid opportunities to learn their job, would gradually[illegible] spread about the country, and would do a[illegible] great deal of good for the industry as a whole[illegible] As to the methods of charging for electricity[illegible] he fancied gas men would have some bad[illegible] headaches if they tried to work on some of[illegible] them. As a matter of fact, they were in many[illegible] cases most unfair to small consumers, who[illegible] were having to pay for the benefit of cheaper

terms for large consumers. He thought that very few electricity users really knew what they were having to pay. In answer to the request for further information as to waste-heat boilers, he would mention that Messrs. Wilsons & Mathiesons had had a great deal to do with designing a very good waste-heat boiler which was on the market. In his remarks in the paper, he had the boiler of Prof. Bone in mind; and he was sure there was a great future for this when it became more fully developed. He was delighted to hear his own meter inspectors speak in the discussion. They could do a great deal, but a point to be gone into thoroughly was the amount of time the inspector could be allowed to spend in booking orders, as compared with the time he must spend on his primary duties. In the main, one found by experience that people wanted the best article, and would pay the price for it. This was satisfactory from every point of view, because it meant that the public became pleased with gas service generally.

Mr. F. Lodge (Wakefield) proposed a vote of thanks to Mr. Mottram for his paper, and to the members of the Gas Committee for their encouraging presence throughout the meeting.

Mr. A. Plews (Bradford) seconded the vote; and

Mr. Mottram responded.

It was announced that the next meeting would be at Elland on May 13, and that in June there would be a visit, jointly with the Manchester District Circle, to the Leeds Works of Messrs. Wilsons & Mathiesons, Ltd.

Lancashire District—Manchester Section.

A meeting of the Circle was held on Wednesday, March 25th, in the Houldsworth Hall, Manchester—Mr. J. H. Sillitoe, Chairman, presiding.

An address was given by Mr. Hamilton Davis, B.Sc., of Leeds, on

GAS v. ELECTRICITY.

[Summary.]

It was pointed out that, in this country, electric current, in the vast majority of cases, is generated by the combustion of raw coal under boilers, and that in consequence a certain degree of atmospheric pollution results and the potential valuable bye-products are destroyed. The average efficiency—allowing for transmission loss—of the process was stated to be between 7 and 8 p.ct. The average efficiency of gas production is between 50 and 60 p.ct., and the efficiency of carbonization from 70 to 80 p.ct. The importance of a knowledge of the thermal value of an electrical unit—namely, 3414 B.Th.U.—was emphasized.

Gas and electric fires were next considered in some detail. It was pointed out that, though the latter depend chiefly for their heating effect on the emission of radiant energy, they are incapable of supplying the motive force necessary for the adequate ventilation of an occupied apartment. The number of requisite air changes per hour was mentioned; and it was stated that the ventilating type of gas fire fulfilled these requirements, and at the same time supplied ample warmth, chiefly in the form of radiant heat. The question of initial cost was considered; and it was shown that the advantage to the consumer in this respect lay very decidedly with the gas appliance. Running costs, on the basis of 1d. per unit of electricity and 9d. per therm of gas, for gas and electric fires were compared; and it was demonstrated that, taking competing fires of equal heating capacity, the cost of current was between two and two-and-a-half times that of the gas consumed.

The heating elements of the electric fires are fragile in comparison with the parts of the gas fire. When installed, the latter requires but little attention, and any necessary adjustments can be made *in situ* without any disturbance to the consumer.

Gas and electric cookers were next compared; and it was stated that the highest-grade gas cooker was a far less costly appliance than an electric cooker of distinctly smaller capacity. In addition, the construction of the latter necessitated a degree of delicacy and complexity not found in the gas appliance. Before results of comparative tests were given, it was mentioned that consumptions of electrical energy had in all cases been measured by a specially tested watt-meter.

The construction of a typical electric hotplate was described; and it was emphasized that, in carrying-out water-boiling tests, the condition of the base of the kettle was all important. To obtain the best results with the electric hotplate, the base of the kettle used should be dull black, in order that the radiant energy from the heated resistance elements should be freely absorbed.

All data given were obtained using kettles with dull black bases. The cost of electricity for heating water to boiling-point was found to be between four and five times the figure obtained when using gas, and the time taken was 60 p.ct. longer with electricity. The latter consideration is of importance to the housewife or cook. The two types of drill were examined; and careful comparative experiments failed to show that a smaller weight loss of meat occurred in the case of the electric grill. The reverse effect was found, due to longer time required, on account of the lower temperature of the electric, as compared with the gas, grill.

Passing on to a consideration of the electric oven, it was mentioned that among the chief claims advanced on its behalf were the following:

1. That by employing the same oven and switch position, the same oven temperatures were invariably obtainable.
2. That the electric oven required no watching.
3. That weight loss—especially in the case of joints—during cooking was reduced.

Dealing with the first of these, it was pointed out that this apparent truism, when translated into a claim for the electric oven as a cooking appliance, depends on the assumption that the various switch positions provided correspond with the diverse cooking temperatures required in practice. This is not always found to be the case. During the cooking of a joint, for example, it is necessary to alter frequently the switch position, if a steady rate of cooking is to be maintained. It appears doubtful whether the electric oven is sufficiently flexible. The gas oven, on the other hand, provides an almost infinite range of cooking temperatures.

With regard to the second claim, extracts from a card of instructions actually supplied with an electric cooker were quoted, in which manipulation of the oven-switch, and the necessity for changing the position of foodstuffs during the cooking process were definitely specified as necessary. On these grounds, it was felt that this claim could not be maintained, and the electric oven compared unfavourably with the gas oven fitted with an automatic temperature-controlling device. This latter eliminated all attention as regards the regulation of oven heat.

The third claim was critically examined and shown to be highly improbable on common-sense grounds. When submitted to tests for two typical cooking processes—namely the baking of bread and the cooking of meat—it was found to be without foundation. For the same degree of cooking, the same weight loss was found in the case of the gas and electric ovens compared. It was strongly emphasized that, to ensure an accurate comparison, the same materials should be taken, and a similar procedure adopted for both ovens. The cost of cooking in the electric oven, on the basis of the charges for current and gas already mentioned, proved to be approximately three times the figure obtained when using gas.

Discussion.

The Chairman said his experience was in agreement with that of the lecturer.

Mr. Robinson (Altrincham) remarked that electric cookers had been installed in his district, but had yielded results inferior to those of gas cookers.

Mr. Barker (Manchester) thought that one advantage of electric cookers was that no products of combustion were formed.

Mr. Davis said that it must be borne in mind that gas cookers were for the most part installed in houses which had been designed for cookers using coal as a heating agent.

Social Evening.

Members of the Circle assembled at the Mitre Hotel, Manchester, on Wednesday, April 8, for a social evening. Mr. J. H. Sillitoe presided. After supper there was a musical programme.

In the course of the evening a cheque was presented to Mr. A. Gilson, the Hon. Secretary, in recognition of his zeal and efficiency in the discharge of his duties.

Mr. Gilson gratefully acknowledged the gift, and paid tribute to the Chairman and Committee for the help they had always given him.

The musical entertainment was furnished by the following: Messrs. J. Fitton (Oldham), R. H. Garlick (Salford), A. H. Williams (Chester), P. H. Christian (Southport), J. F. Proctor (Manchester), and Brown.

The health of the Chairman, proposed by Mr. J. B. Stewart (Rochdale), was heartily received, and was acknowledged by Mr. Sillitoe, who said that what he had done had been a real pleasure.

APRIL MEETING.

A Meeting of the Circle was held at Liverpool on Wednesday, April 22. The first item on the programme was a visit to the Gas Company's Showrooms in Duke Street. Mr. W. B. Payne, Distribution Superintendent, welcomed the visitors, and he and his assistants conducted them over the showrooms, where there was a fine display of appliances.

The main offices are very imposing, with their Corinthian columns, beautifully-tiled floor, and ornamental roof and central dome. The hall and the floor space of the main office are used for the display of hire goods; and switches are fitted for demonstration purposes. One room is devoted to gas-heated hot water apparatus and appliances used for industrial work. The main showroom contains a good selection of lighting, cooking, and heating apparatus. The meter and general repair shops are also well equipped.

As illustrating the progressive spirit of the Liverpool Gas Company, it may be mentioned that they have taken additional premises in Lord Street, Liverpool, for the display of their goods. Lord Street is in the shopping centre of the city.

A visit was next paid to the showrooms, in Bold Street, of Messrs. John Wright

& Co. Here the visitors were welcomed by Mr. Thompson (the Chief Salesman) and other representatives of the firm. Attention was directed to the "New World" gas cooker.

Later the members of the Circle assembled in the Engineering Society's Rooms, Liverpool, under the presidency of Mr. J. H. Sillitoe, of Manchester. Mr. W. B. Payne opened a discussion on "Gas Lighting," and Mr. C. Dickens (Manchester) spoke on "The Outdoor Salesman." Interesting discussions followed. Mr. Payne's paper was illustrated by a series of lantern slides.

Southern District—Kent Area.

A Meeting of the Circle was held on March 11, at the Offices of the Deal and Walmer Gas Company—Mr. P. PICKERING presiding.

Mr. J. F. TYNDALL (Manager of the Company) extended a hearty welcome to the members of the circle.

Mr. E. H. DUNN (Deal and Walmer Gas Company) read a paper on

GAS SALES—A FEW SELLING POINTS.

To increase gas sales, we must sell reliable gas appliances and give satisfactory service. In our Company prior to 1919 we did practically no fitting work. Fittings sales and chargeable fitting work up to 1919 were *nil;* in the year ended June, 1924, they amounted to nearly £3000. We feel confident that we shall exceed this figure during the current year.

FREE INSTALLATIONS.

We have a system in force called the "slot installation." Under this we lay a gas supply to a house, fix a meter, three lights, and a ring—or, alternatively, two lights and a cooker—free of initial cost. The charge for gas is the ordinary prevailing price—*plus* 3d. per therm. The maximum length of pipe run free is 50 ft. The hire of the gas cooker is paid separately—so much per quarter, according to the size.

PUBLICITY.

The following are a few of the ways in which we endeavour to keep ourselves to the fore:

Fortnightly advertisement in the local paper, on lighting, heating, or cooking.

One page in the entertainments programme every season. (There are from 30,000 to 35,000 copies printed.)

One page in the Lloyds "Memorial Homes" Booklet.

An advertisement on the back of our residual and fittings billheads.

When possible we make use of "B.C.G.A." literature, such as "A Thousand-and-One Uses for Gas," which we distribute locally.

We circularize hotels and boarding-houses with pamphlets advertising gas-fire meters, &c., for sale outright only.

The local schoolmasters and private schools are supplied with "Gas Notes for Teachers."

At Christmas time fifty packs of playing cards and three dozen calendars are distributed with gas advertisements on them.

I should like to draw your attention to one point which I feel comes within the salesman's sphere—that is, the selling of coke-burning apparatus. In cases where a consumer, on account perhaps of fuel cost, refuses to have (say) a gas circulator, the fixing of a coke boiler should be advocated. The selling of coke helps to reduce the price of gas.

We have a burner maintenance scheme, which we hope will be a great success in the near future.

It is desirable to have definite periodical entry into a house, to regulate the burners. Often a customer will not trouble about his fittings when they require attention, but blames the gas company for any defect. An inclusive price is charged for material and labour. We also put a small advertisement on the back of the maintenance form.

We employ the part services of a lady demonstrator. This lady circularized the whole district with a letter and a reply postcard asking householders if they had any difficulties with their cooking apparatus. This constituted an excellent method of ensuring satisfaction and introducing new customers.

To condense the foregoing:

(1) An undertaking must supply the very best material and give the best service.

(2) The showroom must be properly equipped.

(3) Advertising must in no way be stinted.

(4) There must be a full and complete co-operation between the staffs, and salesmen should be enthusiastic, energetic, and capable.

The CHAIRMAN voiced the thanks of the meeting to Mr. Dunn for his paper. He also thanked Mr. Tyndall for the welcome given to the Circle, and the Directors of the Deal and Walmer Gas Company for their hospitality.

A New Point of View in Gas Cooking.

(See Illustration below.)

The complete departure from the design of all existing models of their gas cookers evidenced in Wright's new "Eye-Level" cooker requires but a glance for its full justification. To have under the eye, on one level, all the operations of cooking the various parts of a dinner, makes this task very much simpler and quicker. The stooping, the lifting of heavy joints, &c., and the necessity for standing in front of a heated oven to manipulate pans on the hotplates are entirely obviated. With the "Eye-Level," cooking becom a genuine pleasure, to be enjoyed witho any of the fatigue or irritation which we previously inseparable from the kitche range. From the housewife's point view this is ideal; and it is not to b wondered at that the demand for this typ of cooker is on the increase.

Wright's "Eye-Level" cookers hav high-efficiency hotplates of the open typ (the half-solid top is supplied at a sma extra charge) giving high efficiency an real economy. The addition of the warm ing chamber in these models is an impor tant feature. A small independent burne keeps this at a suitable temperature an uses little gas. There is no doubt tha where the extra kitchen space is avail able, the "Eye-Level" cooker will be come popular. This type is made in si sizes, the width of No. 1464 (the smalles size single oven type) being 3 ft. 6 in. while the maximum over-all width of th largest size (double oven) is increased t 5 ft. 11 in., thus affording a wide choice Where it is possible to take out the coal fired range and substitute the "Eye Level" in the recess, this, when neatly installed and suitably tiled, gives the kitchen a smart appearance.

Attractive literature illustrating and describing the cooker will be forwarded on application to Department "A," Messrs. John Wright & Co., Essex Works, Aston Birmingham.

Any Buyers?

In the "For Sale" column of the "Chichester Observer" for April 22, the following advertisement appeared:

FOR SALE.—Small ELECTRIC COOKING STOVE, £1 10s.; or would exchange for small Gas Stove.—ROGERS, George Street, CHICHESTER.

We shall not make a charge for the additional publicity given to the advertisement.

The "Eye-Level" Cooker.

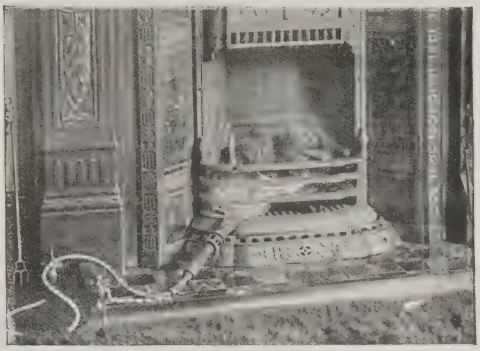
The "Bland" Poker Burner.

Last month, in a paper which he read before the Southern District (London Area) Gas Salesmen's Circle, Mr. A. Tennant, of the Croydon Gas Company, drew attention to the poker burner, which, he said, fulfilled a very useful purpose. In the discussion which followed, Mr. W. J. Sandeman, also of the Croydon Company, referred to the poker burner as an excellent appliance; it gave an opportunity for piping houses throughout. [An account of this meeting was published in the "Salesman" for March 25, p. 64.]

In view of this, salesmen will be interested in the accompanying illustrations of the "Bland" poker burner, which eliminates the time and expense of laying paper and wood, and enables one to kindle a fire almost instantly by simply placing the lighted "poker" beneath the solid fuel. Dying embers can be immediately enlivened.

The burner is connected to a gas tap (fixed at the side of the grate) by a strong flexible metallic tube, and can be inserted into, and withdrawn from, the grate at will.

The burner is manufactured by the Bland Light Syndicate, Ltd., No. 29, Little Trinity Lane, London, E.C. 4.



"Bland" Poker Burner in Use.

Southern District—Sub-Section "B."

The Monthly Meeting of the Circle was held at Portsmouth on Thursday, March 12—Mr. J. Lucas (Chairman) presiding.

CINEMA ADVERTISING WITH ILLUSTRATIONS BY SLIDES.

By M. Tyler, of Chichester.

Advertising is a real handmaid to salesmanship; and in its several forms a most useful one. I would mention two such forms:

General.—Such as advertisements in the public Press, and the modern artistic posters.

Personal.—The printed message sent by post, the poster stamp, &c.

Our subject to-day has about it an element of both; being general in its appeal at a public assembly, and personal in that the pictorial message has its own appeal for each individual present. This form of advertising is not solitary in its appeal—by which I mean it can be run in conjunction with either of the foregoing methods of advertising, it can be made to supplement general and personal advertising, or it can be used in connection with a speciality display in the showroom. The various methods employed in salesmanship and advertising are interdependent; and all must be consistent if real success be desired.

We are very much in the position of the old-time trader taking his goods to market. Our market to-day, however, is any place where we can influence public opinion; and the cinema, if properly used, can, I think, be made a very effective medium to this end. We say that personality means much in the make-up of a salesman. Well, even in the method of securing business by cinema advertising, personality has still to be expressed. In this case our picture and the message accompanying it should suggest talent and the live mind behind the production. Then we shall have maintained personality. We must not be content with an average second-rate slide. It is agreed that a salesman must be versatile. This, in principle, we obtain by arranging our slides to influence as large a variety of minds as possible. A point to remember—and a very important one, too—is that the impression we seek to make is confined to a matter of moments only.

It is in a sense a branch of suggestive salesmanship, for if by knowing our goods we can, by our initiative in sensing customers' needs, strike the popular imagination, and provoke it to think over the subject of the picture screened, we shall have done well in this new form of business getting. Above all things, we must remember that our object is to create interest; and this by tact, good humour, and sincerity, remembering that it is not only what we show, but, what is equally important, how we show it. A shoddy advertisement surely dubs the speciality accordingly, and lets the goods down.

The question of cost must be taken into account in any proposition, but in my opinion this is negligible in relation to the many silent messages sent home. I am of opinion that the cumulative effect in helping to mould the community sense in favour of gas is worth more than the price paid. In our case, it is £3 10s. for six months, which, at three showings a day, represents 468 projections—or just under 2d. each, *plus* the actual cost of slides, which has averaged 3s. 6d. each.

Another matter we should do well to bear in mind, for it is regarded almost as a point of honour in well-conducted businesses of the country to-day, is never to decry a competitor's goods and service. We in the gas industry are one of several public utility services having a thoroughly good commodity, and it is up to us to bring it before the public solely on its merits. We have a good case; let us then be enthusiastic over it, and our enthusiasm must overflow into our advertisements. Only business secured on its merits can be maintained in face of keen competition.

Mr. Tyler then exhibited and explained a series of fifteen slides which were used for cinema advertising in his district.

Discussion.

The Chairman mentioned that the short paper was a new departure for the Circle, and congratulated Mr. Tyler on both paper and slides, which he considered very apt for the purpose in view. He suggested that many companies should follow the example.

Mr. A. J. Garward (Portsmouth) congratulated Mr. Tyler and the Chichester Gas Company for their consistency in keeping gas before the public. It was very difficult to trace results from this method, but, like all good advertisements, it must bring its reward. His Company had not adopted this system; but a series of slides shown on theatre frames had been tried; and this cost 4s. per house per week.

Mr. Davis (Gosport) said that, while his Company had not adopted this method, they ran an advertisement on cinema programmes and screens.

Mr. Tyler replied to questions raised, and said that Chichester regarded it as a point of honour not to decry another man's goods.

ONE WAY OF DEALING WITH A ROOM WITHOUT A FLUE.

By J. Monk, of Winchester.

Often an inquiry is received for someone to call with regard to a gas fire required for a spare room. On calling, the Company's representative is shown the room; and he at once notices that there is no flue. He points this fact out to the consumer, and is told "I want one of those fires to stand in the middle of the room, as exhibited in so-and-so's shop," or "as advertised in such-and-such a paper." I know all of you here, or most of you, have met this sort of thing on your districts; and I will briefly tell you how I have successfully dealt with this question on my district.

I have explained to the consumer why I would not fix the fire asked for, and also that I could not lay on a supply of gas for the consumer himself to fix the fire. I have then asked for an open order to supply and fix a gas fire, and guaranteed satisfaction, ascertaining the most suitable corner of the room. In one corner I fit a stone slab, as used under cookers, and stand the fire on the slab across the corner. To the fire I fit a Urastone flue elbow, to take the flue nozzle of the fire, and continue with Urastone flue piping up the inside of the room, then break through the wall to the outside as near the ceiling as possible, and then carry on outside as with a geyser flue, fitting a cone top or suitable cowl as required.

It is important that all the flue should be of Urastone, from the points of view of utility, heat retention, and lack of condensation. Urastone can be painted to match any interior decoration. On all

these points it leaves sheet-iron flue piping out of the question. To make a good finish to the job, the corner could be boxed-in with plain Uralite sheeting above a mantel-board, and tile-pattern Uralite behind the fire below the mantel-board. In other words, we make a fireplace.

If it is required that the fire shall be fixed against the wall, instead of across the corner, a rectangular-pattern flue can be used. Where the room is on the ground floor, the flue can be carried through the room above before breaking through to the outside, as I believe in keeping as much flue as possible inside, for retaining the heat and assisting the chimney draught.

I have fitted several fires in this way on my district, and have yet to receive a complaint. It is advisable to obtain an open order for this work, as local and atmospheric conditions may require experiments with the flue work outside the building.

Discussion.

Mr. ELLIS (Chichester) raised the question of proper ventilation, and explained the method adopted at Chichester. He said they found that, as the flue pipe warmed, the increased velocity of flue gas put matters right.

Mr. MATTHEWS (Portsmouth) asked what the cost of fixing gas fires as explained amounted to. First cost was often a deciding factor in these cases.

Mr. MONK briefly responded to questions, and gave the cost of fixing.

The members were afterwards entertained to tea by the Directors of the Portsea Island Gas Light Company.

SITUATIONS VACANT.

9d. per Line—Minimum, 4s. 6d.

COUNTY BOROUGH OF BURNLEY.
(GAS DEPARTMENT.)

APPLICATIONS are invited for the Position of SHOWROOM MANAGER and INTERNAL FITTINGS INSPECTOR in the above-mentioned Department.

The commencing Salary will be £307 per Annum, and will be governed by the Corporation's Grading Scheme, Grade D.1. which has at the present time a maximum of £351. These amounts include Bonus, which Bonus is liable to fluctuation in accordance with the cost-of-living figure.

Applicants must have had previous Experience in this class of work.

Form of Application, with Conditions of Appointment, must be obtained from the Gas Engineer, Gas-Works, Burnley.

Applications must reach the Gas Engineer, Burnley, on or before Wednesday, the 13th of May, endorsed "Gas Showroom Manager."

APPOINTMENTS & PROMOTIONS.

Gas Salesmen, Showroom Attendants, and Manufacturers' Representatives are invited to send information as to promotion or changes in appointment for publication under this heading.

NOTICES.

Copies of this Supplement for Distribution among Members of the Gas Sales Staff, can be obtained at the office of the "Journal." Price per 100, 35s.; 50, 18s.; per doz. 4s. 6d.—plus postage; single copies, 5d. (stamps for single copies with order).

The Supplement is published on the Last Wednesday of each Month.

The Editor reserves to himself the right to delete from, or modify any, communications submitted dealing with matters of a purely personal nature.

All communications should be addressed to

WALTER KING, Ltd.,
"Gas Salesman" Supplement,
11, Bolt Court, Fleet Street,
London, E.C. 4.

Telephone Number: CENTRAL 6055.
Telegrams: "GASKING, FLEET, LONDON."

EDITORIAL.

Wembley Reflections.

Where millions of people go expressly for sight-seeing, instruction by display and object-lesson, and for lighter pleasure, there gas should be. That is the deliberate opinion of the gas industry. It is at Wembley again this year—the possessor of more elbow-room. Thus the Gas Exhibit Committee have been able to offer the public a more varied range of interest than in 1924. Nothing is cramped; and there is ample room for inspection, and for soliciting information, by visitors. The advantage of this has been felt, particularly on days when the attendance is the largest; and attendance does vary considerably from day to day, even at an Exhibition having such world-wide attractions as that at Wembley—the days and hours commonly devoted to leisure naturally yielding the greatest number of visitors. Speaking generally of the Exhibition, it has in several ways been greatly popularized this year. As His Majesty the King stated at the reopening, it has been made "lighter and brighter," and, in accomplishing this, interest has not been sacrificed but has been popularly augmented. Gas salesmen—in fact, all men and women engaged in commercial exploitation and sales work—know the value of this; and therefore, successful as was the Gas Exhibit in its mission last year, there is every confidence that the one this year (especially if Old Sol is in genial mood) will exceed it in good work. The "lighter and brighter" ideal captured the Gas Exhibit Committee, particularly the Chairman of the Executive (Mr. F. W. Goodenough), his fellow-members, and active lieutenants; and they have brought it to bear upon their devisings for this year's display. Not that last year's exhibit lacked beauty and brightness; but, in our opinion, what was then done has been excelled this year. Gas salesmen throughout the country will want to judge, and will find opportunities for judging, for themselves. Their business is to get ideas from all sources; and the exhibit will be a large source of ideas for them. If we give of our own ideas, we never need be ashamed to use the ideas of others. In our industry, we have planted, cultivated, and enjoy the co-operative spirit; and it has become part of our common creed to give and to take in a common cause.

The Gas Exhibit is, of course, for creating impressions upon the public mind which will be of advantage to the industry, to the public themselves, and through them to the nation at large. Nevertheless, here we may look at it from the gas salesman's point of view. Gas salesmen have a good general idea of the magnitude of the industry, and of how it penetrates into the domestic, industrial, and trading life of the nation. Its services are manifold and indispensable. But after a studied inspection of the exhibit this year—not a mere casual run round it—we think every salesman will admit that it has taken him out of his own little world of activity, and brought him, admittedly in a small way, into contact with the work that is being done by the gas industry in the far parts of the earth—in other words, in other quarters of our great Empire. The scenes depicting the uses of gas in our principal Dominions should impress gas salesmen at home. They will be reminded that the work of their fellows in those distant places is of a more onerous character than it is in the homeland. They have not the advantages that we have at home. They have not a "B.C.G.A.," they have not at hand the same plentiful and helpful supply of current literature, they have not Salesmen's Circles for conferences, they have not the same immediate advantage of an extensive choice of types of gas-consuming apparatus that the large market offers in this country, there is not the same scope for business, and withal the price of gas is considerably higher than here. And yet those in charge of the sales of gas in those far-away places show good results from their labours. All honour to them! As salesmen at home think of their successes while viewing one of the features of the exhibit, they will also remember their disabilities, and thank their good fortune that their lot for increasing business is cast in more pleasant places.

Another feature that will strike the salesman is the demonstration of refinement that pervades the exhibit, and which acts as a framework to the vast amount of utility—domestic and industrial—which is on view. In describing a gas exhibit in these times, one has to keep well in mind the points at

which competitive attack is the strongest. The electrical people in their campaign suggest that gas is ill-adapted for lighting, heating, and cooking in the house of modern design. The exhibit proves the contrary in each respect. There is lighting for all purposes. The range of heating appliances shows adaptability for all types of houses and styles of appointment. Cooking is demonstrated in a properly equipped hall for all domestic circumstances as well as (in another part) for large catering establishments, and so is water heating. It is all very comprehensive from the domestic aspect; and it extends largely (by example) into industry and trade. There is no need in the "Gas Salesman" to enter into descriptive detail, in view of the full account given in the "Gas Journal" for the 13th inst. Speaking of catering, in that same issue will be found particulars and illustrations of the large gas equipments that have been adopted by the several eminent firms of caterers for feeding the multitude. It is fine testimony to the preference of experts. There is also mention of the extensive use that is being made of gas in the processes of the various exhibitors; as well as reference to the outdoor gas lighting in the Amusements Park. But this is a digression for convenience.

Another suggestion occurs, looking at the scope of the exhibit from the gas salesman's point of view. It is that those whose occupation is to develop the sales of gas and of appliances must not allow their title to limit them in putting in a good word for the secondary products of the concern they serve. They are "secondary" in name, but highly important to every gas undertaking. The price of gas is being raised in many places. An increase in price is not to the liking of the gas salesman; he prefers to see the price of his staple commodity on the decrease. Like good demonstration of the virtues of gas such as is seen at the Gas Exhibit, a low price makes easier the work of bringing about accretions of business. The main cause of the increase of gas prices just now is the reduced demand and values for secondary products. It is hoped this is only a temporary phase in the industry's conditions. But as the secondary products play such an important part in the price of gas, it is to the interest of the gas salesman, on every opportune occasion, to put in a good word for their use. It will be found that at the Gas Exhibit and elsewhere—ta for instance, at the sign of "The Jolly Jack Tar" not far away—the secondary products of coal carbonization fo gas supply are displayed. The objec is to bring to greater public attentio the bye-products, and to increase th demand for them. The larger and th more permanent the demand can b made, the better; for the supply is o the increase, and we want at any rat the one to balance the other at price which will enable the charge for gas t be kept as low as possible.

From all points of view, the Ga Exhibit is worthy of the industry We admire the vision it contains, an its comprehensiveness in detail and i presentment. It is all well done. Th more use gas undertakings make of i by engendering a desire to see it o the part of visitors to Wembley, th greater will be the success in it mission. Gas salesmen, whereve located, can easily, when in conversa tion with customers, put-in a word re garding the display. It will all help t advertise it.

Cookery Centre at Leamington Spa.

In order to facilitate the teaching of cookery to pupils in the elementary schools of the Borough of Leamington, a cookery centre has been opened recently. The appliances provided comprise a Flavel "1923 E30" cooker fitted with "efficiency" burners, plate-rack, enamelled stand, and hood to remove steam, &c., and a separate hotplate similar to that of the cooker. Hot water for washing-up and cleaning purposes is provided by one of Ewarts' "2D Lightning" geysers. The room is efficiently lighted by one 500 c.p. Sugg "Caterham" lamp.

View of the Equipment.

Single-Line Window Displays.—Writing in the "American Gas Journal," Mr. W. H. Matlack advises those responsible for window displays not to hesitate to use neat price tickets on the goods shown. Such tickets often neutralize the timidity which exists in a large number of window shoppers. Display creates a desire; and known prices often clinch the sale. Back up the window display with a good interior display. Psychologists say that the average person cannot attend to more than five units at a time. This, he says, seems more than reasonable, and is a sound justification for confining window displays to single lines, if results are to be obtained. Getting attention concentrated is the big idea. One is not apt to create a desire until this is done; and unless the desire is created, people will not be induced to pass into the premises. That is the end for which to work.

Notes from the "B.C.G.A." District Conferences.

Competition Points.

Several District Conferences of th British Commercial Gas Association hav recently been held; and many of the state ments made by the speakers at these con ferences show how rapidly the use of ga —both domestically and industrially—is in creasing.

Take the Leicester undertaking, fo example. Last year, Councillor Hilto mentioned at the Midlands Conference, th increase in the sale of gas amounted t 155 million c.ft. At present in Leiceste there are between 900 and 1000 gas engine at work; while out of nearly 68,000 con sumers for all purposes, 60,000 have ga cookers. During the past ten or twelv years, 12,000 gas fires have been fixe either on hire-purchase or simple-hir terms.

Atmospheric Pollution.

As Mr. F. W. Goodenough said, it is t gas and coke that the country can look fo its salvation from smoke. Electricity fo power—for mechanical power, for th term "power" has been used much to loosely by political writers and speakers— is, together with the gas engine, doin much to diminish the factory chimne nuisance; but as a fuel it has no future except for incidental use here and there. I cannot touch the great domestic heatin problem. Gas is the solution of the prob lem which appeals to the housewife, wit coke where cheap solid fuel is reall necessary. Apart from the question of th effect upon health and our national wealth there is the effect on the conditions o labour, both in the home and in industry which gas is able to bring about. The ga industry can honestly say that it has con tributed to the health and well-being o workers by helping employers to provid ideal conditions for their employees. W need to be continually informing the publi of what gas means to labour and th working people of this country.

It is the domestic chimney, multiplie by hundreds of thousands, which is th predominant factor in air pollution. Bu London is showing wonderful signs of im provement in this respect. In five yea

no less than one million gas fires were installed in London houses, which means that probably about one million tons less coal were consumed. Recently Dr. Owens (Superintendent to the Advisory Committee on Atmospheric Pollution) said in a lecture: "Thanks to the gradual substitution of gas fires and other smokeless appliances for the antiquated coal fire, the soot deposit in London last year was only 59 p.ct. of that in 1916.

Progress in Scotland.

From official returns, it is found that for the year 1912 the quantity of gas manufactured in Scotland was 17,301 million c.ft. During the succeeding period of twelve years ending with 1924, the quantity increased to 25,188 millions. The increase, is therefore, 45½ p.ct.; and this has undoubtedly been largely obtained as the result of extended use for domestic cooking and heating, and also for industrial purposes. From a calculation, the remarkable estimate is obtained that, to produce the gas required in 1924, actually less coal was used than in 1912. The figures are: Coal used for gas production in 1912, 1,730,000 tons; and in 1924 (with a 45½ p.ct. increase of gas), 1,679,000 tons.

Costs.

At the Greenock Conference Mr. George Keillor put forward the following comparison of cost for delivering equal amounts of useful heat for various purposes by gas and electricity. The data were obtained on the basis of gas of a calorific value of 410 B.Th.U. at 7d. per therm, and electricity at 1¾d. per unit.

Electric Radiator.—One pennyworth of electricity (crediting radiator with 100 p.ct. efficiency) will give out 2736 B.Th.U. of useful heat.

Gas Fire.—2736 B.Th.U. of useful heat (gas fire efficiency of 70 p.ct.) costs 0·28d.

Electric Geyser.—Five pennyworth of electricity (geyser efficiency 90 p.ct.) will give 15,390 B.Th.U. of useful heat.

Gas Geyser.—15,390 B.Th.U. of useful heat (geyser efficiency 80 p.ct.) costs 1·34d.

Electric Boiling Rings.—One pennyworth of electricity (boiling ring efficiency of 50 p.ct.) will give 1368 B.Th.U. of useful heat.

Gas Ring.—1368 B.Th.U. of useful heat (gas ring efficiency of 50 p.ct.) costs 0·192d.

The main facts emerging from the comparison are:

(1) Heating rooms by electricity requires the consumption of 4 times as much coal as the same service by gas.

(2) Geysers heated by electricity require the consumption of 5⅓ times as much coal as the same service by gas.

(3) Boiling water by electricity requires the consumption of 6½ times as much coal as the same service by gas.

(4) Heating ovens by electricity requires the consumption of 3 times as much coal as the same service by gas.

The output of gas in Greenock will this year exceed 600 million c.ft., compared with 418½ millions in 1913-14 (an increase of 43½ p.ct.

Speaking at the Chester Conference, Mr. Owen Evans said that the average efficiency of gas in actual use for the customary domestic duties is well over 50 p.ct.; and if all the coal at present consumed for domestic purposes was carbonized at the gas-works, no more coal would have to be used, and there would be over 20 million tons of coke to spare, which could be utilized with efficiency, in displacement of coal, for various industrial purposes. There would also be an enormous additional supply of the other bye-products. Or, alternatively, such is the flexibility of the gas-works method, the whole of the extra coke and tar produced could be gasified; and the coal used at the gas-works would be proportionately reduced. On the other hand, if the coal used for domestic purposes were substituted by electricity, the quantity of coal required would be increased threefold—*i.e.*, to the enormous quantity of 120 million tons per annum.

Gas and Electricity for Cooking.

At the same conference, Dr. Harold Hartley remarked that the gas cooker, which has replaced the coal range in millions of cases, offers the cheapest and most convenient means of carrying-out domestic cooking, and is applicable to all classes. A cooker of the present day will show a saving of from 25 to 33 p.ct. compared with those of the pre-war period. It is possible to bake six 2-lb. loaves for 1d., using gas at 10d. a therm. Even with electricity at 1d. per unit, it costs from two to three times as much to cook with electricity as with gas.

The following figures conclude these few notes. They constitute perhaps the best argument in favour of gas.

Output of Gas in the British Isles.

Last year	281,874,000,000 c.ft.
The year before	269,602,000,000 ,,
Increase	12,272,000,000

Number of Consumers.

Last year	8,502,069
The year before	8,406,172
Increase	95,897

Cookers and Grillers Supplied.

Last year	5,450,093
The year before	5,133,190
Increase	316,903

Cookery Demonstrations at Glasgow.

Our thanks are due to Mr. E. Edison Stones, Assistant General Manager of the Glasgow Corporation Gas Department, for the two photographs which are reproduced here. One is an external view of the windows of the showrooms in Sauchiehall Street, Glasgow, showing the number of people attracted to the windows during the cookery demonstrations which are at present being held. The other is a view of the interior of the window. The lady demonstrators are seen at work.

The "interest power" of the display is well indicated by the photographs.

An Elementary Treatise on Gas Lighting.

For the Student Gas Salesman.

[COMMUNICATED.]

CHAPTER 10.

(Continued from p. 84.)

Enough has now been said to indicate that artificial lighting is a keenly-competed business; and while electric light is a strong rival to gas light, the student will do well to remember that it is by no means the *only* competitor. In order that the comparative costs of equal lighting service can be readily calculated, no matter what may be the prices at which gas and electric energy are available, there are given in Table 6 some further data in respect of the now most commonly met-with gas and electric sources. No attempt will here be

TABLE 6.—*Units of electric energy dissipated by two classes of lamps in the production of equivalent lighting service to that given by one therm of town gas utilized in three classes of burners.*

Class of Gas Burner.	Class of Electric Lamp. (1) Metal Filament Vacuum Lamp. (Units).	Class of Electric Lamp. (2) Metal Filament Gasfilled Lamp. (Units).
(*a*) Low-pressure inverted incandescent burner .	5·000	2·640
(*b*) Low-pressure inverted incandescent preheated cluster burner	7·812	4·125
(*c*) High-pressure (80 in. W.G.) inverted incandescent preheated burner	11·960	6·283

NOTE.—Efficiency of gas burners rated in terms of m.h.s.c.p. Efficiency of electric lamps rated in terms of m.h.c.p. The lighting services provided by 1 therm of town gas when utilized in burners (*a*), (*b*), and (*c*) were given in Table 2 as 4000, 6250, and 9520 candlepower-hours, respectively.

made to offer any elementary explanations as to the nature of electricity itself and the methods and machinery whereby it is (as we say by a common misnomer) "generated"—*i.e.*, made available for the performance of work. These involved subjects are obviously outside the scope of this treatise; and it must suffice for us to limit ourselves to a brief consideration of electric light and of the principal methods of applying electric energy to the production of light. Quoting from "Modern Electrical Engineering":†

> "There are various forms of light produced by means of electricity. The sparks from an electrostatic machine, or those from a charged accumulator of Leyden jars, give intense light of which lightning flashes are only a magnified example. The discharge of an induction coil through tubes from which the air has been partially removed gives light of great beauty. Light can also be obtained by passing through a platinum wire a current sufficiently strong to raise it to a red or white heat. But the name 'electric light,' however, has generally been applied to the light obtained from the incandescent electric lamp or from the larger and more powerful light of the arc lamp."

Let us then direct our attention to these two principal kinds of electric light sources, deferring for a few moments any thought of how the light is produced.

INCANDESCENT LAMPS.

For a number of years the incandescent lamp with a filament of carbon (usually referred to as the "carbon glow lamp") held the field; but its efficiency was of the low order of 4 watts per c.p. As time went on, it was found possible to improve upon this poor efficiency by using another substance for the filament; and in the "Nernst" lamp—sometimes spoken of as the "Nernst glower"—an efficiency of about 2·15 watts per c.p. was obtained with a filament of zirconium.* Unfortunately, however, zirconium filaments were very fragile; they were easily broken, and with the advent of the metal filament lamp the manufacture of the "Nernst" lamp was discontinued.

An important advance was made in the manufacture of incandescent electric lamps when it was found that the metals tungsten and tantalum provided strong and suitable filaments which could be run at much higher temperatures than were formerly possible, thereby enabling manufacturers to produce lamps having efficiencies varying from 1·5 watts to 1 watt per c.p.†, according to the size of the lamp. But within recent years the efficiency of the incandescent electric lamp has been still further increased. Gasfilled lamps—known originally as "half-watt" lamps—have been placed upon the market; and they have an actual efficiency of 0·6 to 0·7 watt per c.p.

In this latest type of lamp the bulb, instead of being exhausted of air in the usual way, is filled with argon (one of the rare gases of the atmosphere); and the presence of this inert substance makes possible the attainment of much higher filament temperatures than those obtaining in the case of a filament *in vacuo*. And the new lamp differs in another important particular. The filament, instead of consisting of a number of straight threads, is wound in close spirals. The gasfilled lamp represents on the face of matters a noteworthy improvement upon other incandescent electric lamps in regard to running costs; but to secure this economy of current the intrinsic brilliancy of the source of light has been increased to such an extent as seriously to endanger the eye, should it be exposed for any length of time to the naked filament. Ordinary metal-filament lamps in their unscreened condition are known to affect eyesight adversely; but gasfilled lamps are much more harmful—their "glare" is blinding, and properly to utilize them, their intrinsic brilliancy has to be so much reduced by the use of diffusing auxiliaries that they are not as economical as they may at first appear to be. Metal-filament lamps both of the ordinary and the gasfilled types are manufactured in certain standard sizes covering a wide range. "For the higher voltages (200 to 260) in general use the smallest size is 15 watts, giving about 11 c.p.; the sizes above being 20, 30, 40, 60, 80, 100, 200 watts upwards to 1000 watts." "For the lower voltages (100 to 130) the smallest is 10 watts, giving about 8 c.p.; the other sizes being the same as for the higher voltages." "Miniature lamps may be had in sizes from 1 c.p. upwards, but these are only for pressures up to 25 volts, and must be connected in series when used on higher pressures." [Extracts from "Modern Electrical Engineering."]

ARC LAMPS.

We are told on the authority of the contributors to "Modern Electrical Engineering" that "the candle-power of the open-type arc lamps with opalescent globes while nominally 1000, is not found in practice to be more than 680, taking the measurement at the most favourable angle—*i.e.*, 45°. The modern flame-arc lamp has an efficiency of about 5 c.p. per watt—*i.e.*, the 10-ampère lamp will give a mean hemispherical candle power of 2500 to 2800. The number of hours burning with one trimming may be from 16 up to 18 hours, and they can be run eleven or even twelve in series on 500 volts. If the old type be compared with the flame type, it will be seen what a great advance has been made. In the first place there is about four times the amount of light for the same consumption of energy; and secondly, with one trimming, 120 to 140 hours burning is obtained, as compared with 34 hours. The main feature of the long-burning flame arc lamp is the magazine. Each lamp has two magazines of light sheet-metal construction to hold the positive and negative carbons respectively. In the 120-hour type the carbons are 15 in. long, and fourteen to eighteen pairs go to one trimming. The carbons are held in place by a spring, and are pressed by it towards the inner end of the magazine." "The feed mechanism takes hold of the inner carbon, and gradually, as it is consumed, works it out. When the stump falls out, the next carbon comes into position by the pressure of the spring, and is ready to be fed out, and so on. Arc lamps are generally used for the lighting of large open spaces, workshops with high roofs, railway stations, &c., and, of course, for public street lighting. These lamps are not in general use for the lighting of halls or ordinary interiors. In order to obtain good light distribution, when units of large candlepower, such as flame-arc lamps, are used, these should be placed at a considerable height from the ground. In the case of a 10-ampère lamp of (say) 2800 c.p. the distance should be 30 ft., and of an 8-ampère lamp (say) 25 ft. from the ground—smaller sizes in proportion." "Flame-arc lamps are usually provided with inner and outer globes, and the inners are made to serve a double purpose. First, as the light from a flame-arc is even more concentrated than that of the old type at an angle greater than 45° from the horizontal, it is necessary to deflect some portion of the rays at smaller angles to widen the area of distribution. Makers have adopted inner globes to effect this; some using plain glass, others globes with facets moulded on the outer surface of the glass, and known as dioptrics. Secondly, if the globes have air-tight joints at top and bottom, they serve to protect the outer globes from the fumes from the carbons, which would condense on the colder surface of the outer globes and actually have an etching effect on them, making them in time opaque." "The globes for flame-arc lamps should preferably be of clear glass."

The efficiency of arc lamps varies a good deal according to the size and design of the lamp; and a comprehensive statement of the performances of arc lamps in general (abstracted from "Modern Electrical Engineering") is given in Table 7. The efficiencies of the modern mercury-vapour lamp and neon-tube are also listed; but time does not permit our considering these special sources at further length.

Though the materials and methods employed in the production of artificial light may, on the face of matters, appear different, all the sources listed in Table 5 evolve light as a result of incandescence.

† Prepared under the editorship of Prof. Magnus Maclean, M.A., D.Sc. (1918.)

* Zirconium is one of a group of the so-called "rarer earths," having peculiar powers of light emissivity; and it was referred to in regard to gas mantle manufacture—see Chapter V., "SALESMAN," for May 30, 1923.

† The efficiency varies according to the size of the lamp; but a fair average figure to take is 1·25 watts per c.p. (m.h.c.p. rating).

Table 7.—*Performances of Electric Arc Lamps.*

Type of Lamp.	Current in Ampéres.	Mean Hemispherical Candlepower.	Watts per M.H.S.C.P.
Open arc, continuous current, pure carbons	6 to 15	360 to 1300	0·9 to 0·65
Open arc, alternating current, pure carbons	8 ,, 20	255 ,, 645	1·58 ,, 1·1
Enclosed arc, continuous current, pure carbons	4 ,, 6	315 ,, 595	1·4 ,, 1·1
Open arc, continuous current, flame carbons	8 ,, 12	1890 ,, 3500	0·23 ,, 0·19
Open arc, alternating current, flame carbons	8 ,, 12	1125 ,, 2295	0·37 ,, 0 25
Quartz mercury vapour, continuous current	2·7 ,, 3 5	900 ,, 3600	0·30 ,, 0·22
Neon tube, alternating current	..	..	0·5 (m.s.c.p.)
Moore tube, alternating current	..	..	1·7 ,,

Note.—"In the alternating-current arc, the 'crater' forms upon each of the carbons in turn; and as there are two brief periods of extinction during every cycle of the current, the mean temperature of the carbons is lower than that in a continuous-current lamp. As a result, the efficiency of the alternating arc is lower than that of the continuous-current type. Further, the current taken by an alternating-current arc may be from 10 to 25 p.ct. greater than that taken by a continuous-current arc to which the same electrical power is supplied." (Arthur Blok.*)

The process that is common to all of them is that something is made very hot and shines only because it is very hot." (Prof. Thompson). In other words, light from these sources is a secondary effect of heat. But the amounts of heat-energy required per unit quantity of light produced vary very considerably with different sources—as will be seen from the few examples given in Table 8; and hence the dissimilar luminous efficiencies of various luminants quoted (according to lux) in Chapter 2, "Salesman for August, 1922.

Table 8.

Source.	Energy (expressed in terms of B.Th.U.) Expended in the Production of One Candlepower-Hour.
Commercial (stearin) candle	308*
Paraffin flame-lamp	147†
Low-pressure inverted incandescent gas burner	25
High-pressure ditto	10·5
Ordinary metal-filament electric lamp	4·27
Gasfilled ditto	2·26
Flame-arc electric lamp	0·91

* After Dr. L. Bell's statement of 90 watts per candlepower.
† According to Prof. Wedding.

It is hoped that students will now have appreciated the point that the cost of producing artificial light by the sources referred to in Table 5 is directly related to the cost of generating heat. This explains why electric light is so much more costly than gas light. Though electric sources require to be supplied with far less heat-energy than incandescent gas sources to produce equal amounts of light (for example the gasfilled incandescent lamp expends 2·26 B.Th.U. per candlepower-hour, as against 25 B.Th.U. per candlepower-hour expended by the low-pressure inverted incandescent gas burner), the superior thermal efficiency of electric sources does not make electric light as cheap as gas light, simply because the transformation of electric energy into heat is a far more expensive process than the generation of heat by burning gas. For example, 1 B.Th.U. produced electrically costs, with current at 5d. per kilowatt-hour, 0·001462d., as against 0·00008d. were it generated by burning gas costing 8d. per therm; but, of course, the comparative costs of producing light would not be in proportion to these figures, because, in the case of electric sources, one unit of heat produces more light than the expenditure of a similar quantity of heat by gas sources.

The student will now have observed that the heat required to make light may be derived either by chemical or electrical means. Sources Nos. 1 to 5 (inclusive) in Table 5 are termed combustible illuminants. Heat is generated by combustion—a chemical action described in Chapter 2, "Salesman" for July, 1922; and in all these cases solid bodies, either present normally in the flame or else added to it, are rendered white hot by the temperature of flaming gases.* Sources No. 6 are electrical illuminants. Heat is produced by electric energy; and combustion has nothing to do with the heating effect produced when a current of electricity is forced through resistant conductors. In the case of incandescent electric lamps, fine threads of resistant conductors such as carbon, tungsten, tantalum, &c. (termed the "filament"), are employed to oppose the flow of an electric current; and the energy expended in overcoming this resistance is transformed into heat. The filaments therefore become very hot and radiate light waves; but they do not burn away, because they are placed in bulbs which have been either exhausted of air or filled with an inert gas.

In the case of electric arc lamps of the "ordinary" or "plain carbon" type, "two stout pencils of carbon (known as electrodes), joined by wires to the electric supply mains, are made to touch one another for an instant, and then are parted asunder to about $\frac{1}{8}$ in." "The current forms a sort of flame—called the arc—between the carbon tips; and the tips, particularly that of the positive pencil, become white hot."† "The electric arc consists of a column of conducting vapour which is derived from the substance of the electrodes and conveys the current across the gap between them. With plain carbons the arc itself, although extremely hot, is almost non-luminous . . . and by far the greater part of the light is derived from the small and intensely hot area or crater which forms on the positive electrode at the place from which the arc springs. The candle-power of an arc depends upon the current passing through it, as this determines the area of the crater and the temperature of the glowing tips of the carbons. By enclosing the arc in a glass vessel, so as to retard the rate of combustion of the carbons,‡ the burning hours may be greatly increased, but at the same time the efficiency of the lamp is diminished."§

Coming now to the electric arc lamp of the "flaming" or impregnated carbon type, we find it to be more highly efficient than the ordinary carbon lamp just discussed, on account of the fact that the electrodes are of special constitution, whereby the arc itself, instead of being almost non-luminous as is the case with plain carbons, is rendered highly luminous. "The arc between pure carbon electrodes is exceptional, as carbon is the most refractory substance known, and is one of the very few that passes directly from the solid into the gaseous state at atmospheric pressure. Thus any substance fed into the arc is volatilized, and will give its own spectrum superimposed on that of the arc and carbons; and this is what obtains in the case of the 'flaming' arc lamp." Now the colour of the light given out by the latter lamp depends upon the material fed into the arc. The yellow flame-arc is obtained with calcium fluoride, while salts of cerium and strontium yield white and red arcs respectively. In the manufacture of flame carbons the particular salt selected is mixed with finely-divided carbon, and is made into a paste with potassium silicate; and this mixture is then forced into a cylindrical casing of carbon, and is dried. With flame carbons "the emission of light is far more efficient, as, in addition to black body radiation from carbon—the only useful source of light in the pure carbon arc—selective radiation* takes place, depending upon the materials used, from 30 to 35 p.ct. of the light coming from the arc itself,"† as compared with about 5 p.ct. only when plain carbon electrodes are used. But lest we should be tempted further to depart from our primary consideration of costs, let us conclude this instalment by finally reviewing our tabulated data.

It will be noticed in regard to Tables 5, 6, and 7 that there is no common basis for rating the efficiencies of the various light sources under review. The difficulties experienced in endeavouring to arrive at a standard measure of luminous intensity equally fair in its application to a collection of different sources was intimated in Chapter 9, "Salesman" for July, 1924; and the student wondering why some values are expressed in terms of m.h.c.p. and others in terms of m.s.c.p. or m.h.s.c.p. will probably find this doubtful point answered by referring to certain quotations from Dr. L. Bloch's "Science of Illumination," as given in the July instalment of "An Elementary Treatise on Gas Lighting." The cost figures advanced in Table 5 (relating, of course, to performances of unscreened sources) afford, it is hoped, evidence sufficiently accurate to support in a general way the point made earlier as to the relative cheapness of incandescent gas-light in regard to running costs.‡ But there are matters other than that of relative cost upon which the buyer of artificial light should be informed; and in the next instalment the writer proposes to speak principally of town gas and electric sources in relation to their relative quality, reliability, safety, convenience, and hygienic value.

* See "Elementary Principles of Illumination and Artificial Lighting." (1914.)

* See remarks on luminous flames in Chapter II., "Salesman" for September, 1922. See also remarks on incandescent radiants in Chapter V., "Salesman" for May, 1923.

† Extracts from "The Manufacture of Light." (Prof. Silvanus P. Thompson, D.Sc., F.R.S.).

‡ The combustion of the plain carbons adds nothing to the light.

§ Extracts from "Elementary Principles of Illumination and Artificial Lighting." (Arthur Blok.)

* It is this selective radiation which gives the arc its particular colour.

† Extracts "Modern Electrical Engineering."

‡ Notice that these are costs in respect of producing light and not of utilizing it. The proper utilization of light (the primary function of illuminating engineering) calls for the equipment of light sources with globes, shades, and reflectors; and these accessories reduce the luminous output of sources. Furthermore, the utilization efficiency of different systems of lighting—as for example "direct" and "semi-indirect"—are widely dissimilar; and it has been argued therefore—and rightly so from an illuminating engineer's viewpoint—that relative costs of artificial lighting systems should not be made on the basis of rival unscreened sources giving so many candlepower-hours for so much money, but that costs should be compared in terms of the intensity of illumination (*i.e.*, the number of foot-candles) provided on the working plane by complete lighting systems. Unfortunately, when generalizing, one cannot do this owing to the several varying factors which have to be taken into account when utilizing manufactured light; but wherever possible running expenses, as well as installation costs, should preferably be compared on the basis of providing a predetermined mean illuminating duty. However, the figures in respect of unscreened sources offer an index as to the comparative costs in this latter connection. More will be said later on the subject of utilizing light sources.

(To be continued.)

B.C.G.A. Gas Salesmen's Circles.

Southern District—London Area.

The May Meeting of this circle took place on May 5, at No. 30, Grosvenor Gardens, S.W.—Mr. Stephen Lacey, of the Gas Light and Coke Company, presiding.

The Chairman, in opening the proceedings, said they would remember that, at the Gas Salesmen's Conference at Wembley last year, Mr. F. W. Goodenough stated that there were two subjects which he regarded as particularly suitable for discussion by the circles during the present session. The first was the relative efficiency of heat production and utilization by means of gas and electricity. This question the circle had discussed at an earlier meeting of the session; and he thought the paper he had read on that occasion, and the discussion which followed, had served to remind them all of the unshakable character of the foundations of the gas industry, and had encouraged them to strive confidently for the attainment of the ideal that the "B.C.G.A." had so eloquently and so persistently preached—namely, "Gas as a public service." It seemed to him that the chief value of those phrases—such as "Service" and "The consumer first"—that symbolized this ideal was that they led to an attitude of mind which on the part of the gas undertaking led to a right policy, and on the part of the staff and workmen led to a determination to see this policy translated into action. He thought the "acid test" to-day of right policy on the part of the gas undertaking was to be found in the answer to the question, "What is being done about the inspection and maintenance of gas appliances?" Now the inspection and maintenance of gas appliances was the second subject suggested by Mr. Goodenough for discussion; and those present were looking forward with great pleasure to hearing what Mr. Davis had to say regarding the work his Company had done and were doing in this connection.

MAINTENANCE OF CONSUMERS' APPLIANCES.

By J. Davis, Outdoor Superintendent of the Sutton Gas Company.

Essentials.

A maintenance scheme, to be thoroughly effective, should cover all the gas apparatus installed throughout the consumers' premises, whether their own property or the property of the gas company. The service should be systematic and regular, and, above all, carried out by competent, good-class fitters, who should be courteous, polite, and of good address. The men chosen for the work should endeavour to gain the confidence of the consumer, in order to ensure as far as possible that every facility will be afforded the execution of their duties. In my opinion, if these points regarding the human element are not strictly observed, the scheme is likely to do more harm than good. The consumer will gradually lose confidence in the company, should their workman be tactless and carry out his duties in an inefficient manner.

The fitter should be thoroughly conversant with all gas appliances, so as to enable him to answer any questions intelligently that may be asked by the consumer, as even to-day it is really astonishing what little knowledge some of the consumers have of their apparatus. He should also be instructed to give special attention to all wearing parts, such as taps, cup-and-ball joints, and water-slide chandeliers, as it is generally from such sources as these that minute leakages occur which are a nuisance and danger to the consumer, and an inducement for them to contemplate the introduction of electricity.

Objects.

Let us consider the objects of maintenance as applied to a gas company. It is to ensure that the consumer's appliances are maintained in a thoroughly efficient condition, scrapping, as far as possible, all obsolete apparatus, eliminating leakages, and encouraging the use to the fullest extent of the gas apparatus installed; increasing consumption, and incidentally increasing sales; and, furthermore, ensuring a satisfied consumer impressed by the fact that he or she is being served by a company out to give "A1" service. To my mind, a most important point is gained in satisfying the consumer, who immediately becomes the company's best advertising medium.

I am convinced that, without some form of maintenance, gas appliances cannot retain their efficiency for any length of time. It is a well-known fact that numerous consumers throughout the country are dispensing with gas appliances due to the fact that such appliances are not giving efficient and economical duty. In order to maintain our business, we must go to the consumer, and not wait for him to come to us. I am firmly convinced that a maintenance system, however modest, is *the* method of securing the object in view. We have all experienced the consumer who will not trouble to complain, but simply sends a note saying: "Take out your gas appliances, as they are of no use."

Cost.

The question of bearing the cost of the system is debatable on many points. In my opinion, all labour should be free; no charge being made for renewals to the company's property, and only a moderate charge for renewals to the consumer's own appliances. The cost of labour and upkeep of the company's property on the district should be included in the price of gas, as a maintenance system should eventually benefit every consumer, whether supplied by ordinary or prepayment meter.

Sutton Maintenance Scheme.

Now I propose to give you some details of a scheme recently brought into operation at Sutton.

In November, 1924, after careful consideration, the Sutton Company decided to initiate some form of maintenance; and, after much discussion, it was arranged to adopt a combined survey and maintenance. This at first may appear a somewhat ambitious scheme; but it was found necessary for several reasons, known to most of you —*e.g.*, difficulty experienced in keeping accurate records during the war. It was therefore decided that at the time the survey was made the fitter should also make minor adjustments to the gas appliances. This we have proved to work extremely well.

Anything found to be more than ordinarily difficult, or involving the expenditure of a lot of time—such as overhauling circulators or changing obsolete apparatus —is made the subject of a report; and after the necessary arrangements have been made with the consumer, a fitter is sent to execute the job *in situ* or, if necessary, to bring the apparatus to the works.

A card system was decided upon as being the most suitable method of keeping records for our district. The card, 6 in. by 4 in., is filled-in from the existing records, and then checked and corrected by the maintenance fitter; the consumer's own appliances being added after inspecti The cards are indexed and filed in str order, so that they may be easily follow up for propaganda purposes.

A suitable letter was sent to every c sumer. Each letter was signed by Engineer and Manager personally, as was felt that the consumers would rea letter bearing a "live" signature, and consign it to the waste-paper basket— resting place of most circular letters.

About one day is allowed to elapse; a then the fitter calls, and examines and every gas appliance throughout house, including main cock and met He renews all worn parts of the applian where necessary, paying particular att tion to wearing parts such as taps a cup-and-ball joints. He is also instruct to see that the service and meter adequate for the work they are called up to do. Where water-slide chandeliers found to be in use, a modern fitting is su gested at a reasonable price, or alterr tively an offer made to convert the wat slide into a fixture free of charge, th securing the consumer and the Compa against leakage. Labour is free; and or a moderate charge is made for renew to consumers' own appliances. Before newing any parts, the consumer's defin consent is obtained, in order to avoid subsequent dispute.

The fitter has a schedule of prices, that he is in a position to state what t renewals will cost. He is also provid with a receipt book for consumers w wish to pay cash. In fact, we express preference for this method, in order to r duce overhead charges, book-keeping, & to a minimum.

The receipt book is in triplicate, mad up in three colours—white, pink, and blu The white slip is given to the consume either in the form of a receipt if he pa cash, or as a delivery note if he desir credit, the fitter retaining the two dup cates; the pink slip being returned wi his card, while the blue one he retains f his own protection in the book. We ha been complimented by many consume on this being a businesslike method, as receipt is given for cash. Should credit desired, the slip is returned to the consum marked "To enter," so that when t account is rendered there is no dispu with regard to materials used.

From this census and survey it is i tended to develop a seasonable mainte ance, giving special attention to hot wat and cooking appliances in the early sprin and heating and lighting appliances in t early autumn.

Personnel.

The fitters selected for the scheme a men of good address, courteous, and polit and are thoroughly versed in the work r quired of them. They are given speci training in the shops; theoretical and pra tical tests being applied, to judge their su ability for the work before being sent o to the district. They are taught the el mentary principles of salesmanship, t assist them in the introduction of new an up-to-date apparatus, where found neces sary or desirable; and I am pleased to b able to say reports have been received fro time to time which reflect credit on th men employed on this work.

Costs of the Scheme.

The costs of the scheme or system a very difficult to arrive at accurately at th moment, as though a full return is mad of the materials used and time taken, th costs can only be determined approxi

tely, as the latent results from such a eme are without doubt very considere. Furthermore, our experience points a considerable reduction in complaints, reased profit from sales of appliances, l, what is perhaps more important, we ve undoubtedly succeeded in gaining the ifidence of the consumers, as they lize we are out to ensure that every ap- ance is giving efficient service.

Up to April 18, 1925, the amount spent wages was £68 3s., and the number of ises visited 441, which works out at ap- ximately 3s. 1d. per consumer. This ount cannot be taken as a definite rking figure, as the scheme has only n in operation a short time. Over a ger period this sum—3s. 1d. per con- ner—will without doubt be considerably uced. Taking the average consumption consumer per annum, we estimate the t at approximately one-fifth of a penny therm sold.

The number of appliances attended to is follows :

inary meters .	441	Boiling rings . .	16
okers . . .	401	Radiators . . .	21
es	796	Lamps	2
vsers . . .	39	Gas irons . . .	7
culators . .	56	Check slot meters	10
sh coppers .	34		
mers . . .	570	Total . .	2393

The number of new appliances sold or on hire is :

okers . . .	5	Geysers	3
es	10	Wash coppers. .	5
irons . . .	1	Circulators . .	1
liators . . .	1	Lighting burners .	21

l various sundries such as mantles, globes, &c., the value of £3 os. 9d.

In conclusion, I would say I am con- ced that, owing to the keen competition sting to-day, and which will undoubtedly come still more keen as time goes on, very life of gas companies in the future ll be determined by the attention given consumers' appliances, as it is unlikely consumer with satisfactory appliances ll readily spend money on installing ne other form of lighting, heating, or oking ; but the consumer with inefficient pliances will most certainly turn-over to ctricity without even bothering to con- lt the gas companies to ascertain ether some improvement cannot be ade in his gas apparatus.

I am indebted to my chief, Mr. Henry age, for his kind permission to present rticulars and figures.

Discussion.

The Chairman remarked that Mr. Davis s to be doubly congratulated—first, on having oduced an excellent paper on a subject of vital portance ; and secondly, on serving a pro- essive Gas Company. They were glad to wel- ne at the meeting Mr. Henry Gage, the gineer and Manager of the Sutton Gas Com- ny, who had kindly consented to open the iscussion.

Mr. Henry Gage (Sutton) said Mr. Davis's tention in presenting the paper was to pro- ke a discussion. He felt that it dealt with subject which was of vast importance to the lustry to-day. It was not necessary to go ck very far in the history of gas undertakings come to the time when all the literature alt with "What can we do in the retort use and to the various apparatus on the orks to improve their efficiency?" Very tle was at that period said about distribution the burning of the gas when it got to the nsumers' houses. As time went on, how- er, partly owing to the competition of elec- icity, the industry began to realize that, if was desired to improve the position and in- ease the output, it was necessary to attend t only to the works but to the consumers. here was room for men of ability to take up is side of the undertaking, so as to ensure at the consumers were thoroughly satisfied. irectors were gradually led to see that it was paying proposition to appoint such men. ne scheme that Mr. Davis had outlined had en in operation only a very short time ; but ere was no doubt that it would give great tisfaction to the consumers in Sutton.

Mr. C. Harford (Grays and Tilbury) re- arked that no doubt the author had already noted a great falling-off in the use of the phrase "bad gas," or of complaints generally, as the result of his men going round. Did the amount quoted as actual wages paid to maintenance fitters include any supervision? Also, was his scheme extended to slot consumers? If not, he thought it was a pity. The sale of sundries appeared rather low over a period of five months. Per consumer, his (the speaker's) figures were considerably higher. They had a rather different scheme in Grays of getting their costs out ; they worked them out, not per consumer, but per fitting—lighting burners and apparatus of all descriptions. The cost on gas of one-fifth of a penny per therm sold was a somewhat high charge for maintenance. Mr. Davis did not say how he intended to carry on the scheme—whether by monthly or quarterly visits. At Grays they had a system of monthly visits, and found it worked very well.

Mr. A. J. Garward (Portsmouth) said that in his opinion the very fact that most gas companies did a certain amount of free maintenance proved the necessity for a general maintenance scheme. In addition to keeping the manufacturing plant up to date, it was absolutely essential to go right through to the burning-point of the gas, though he was afraid with a very large number of gas undertakings this had not been attempted. With the competition there was now, it was necessary, not only to sell gas, but to give the consumers service at the same time. The only way to do this was to adopt some plan such as the excellent scheme put into operation at Sutton. Did the men who went round attend to incandescent burners during their visits? Also did they look after industrial as well as domestic consumers? Again, did the cost of 3s. 1d. per consumer include attention to hired appliances and the replacement of parts? Some time back his own Company recognized the necessity for a scheme at Portsmouth. They went into the matter very carefully, and decided to experiment with a certain number of houses. They first did 5000, and had since done another 5000 ; and on inspection they found that, taking these 10,000 houses, there was an average of 4·74 defects in each. By "defects," he meant there were this number of faults. It might have been an escape, or a geyser not working satisfactorily. It might have been a cooker that required parts, or some adjustment ; of it might have been a water-slide chandelier which they recommended should be exchanged or made stiff. The cost of this work to date had averaged 2s. 2·80d.—cost of labour 1s. 11·5d., and cost of material 3·39d. This material was included in the cost because it was "free material." When the fitter went round he adjusted hired appliances ; but if any parts were required he noted the fact on a form, and the parts were then delivered and fixed by a separate department. Mr. Davis called his paper "Maintenance ; " but what he had undertaken might be regarded as a "primary inspection." This first visit, he suggested, would prove more expensive than subsequent ones—which he would term "maintenance visits." Therefore the author could look forward to the costs being considerably reduced later on.

Mr. Davis replied that since the starting of the maintenance scheme the phrase "bad gas" appeared to have been dropped altogether ; while complaints generally had been considerably reduced. The figures did not at the moment include cost of supervision ; and they had not so far extended the scheme to slot consumers, though eventually they hoped to cover the whole district—both slot and ordinary. No doubt they would eventually get the price of 3s. 1d. down to a very much lower figure. One-fifth of a penny per therm was only a rough estimate ; and he thought the service was well worth it. Sutton, of course, was a purely residential district. They took the whole house, from top to bottom. The cost given in the paper for labour included renewal parts of hired appliances.

Mr. Garward thought a six-monthly or even a three-monthly period was too long to let incandescent burners go. It became a question whether one should not have a separate system for burners.

Mr. L. H. Holland (North Middlesex Gas Company) said his Company had started a scheme within the last few days, and he thought it was working out very successfully. They had visited Brighton, where there was one of the finest schemes in operation. How many visits per day did the men at Sutton put in, and how many men were there on the work? The preliminary circular-letter was a good idea, in order to ensure admission of the fitters to the houses, though his Company's fitters had not experienced any difficulty in this way.

Mr. Davis answered that jobs varied considerably. Sometimes men did only two per day, and sometimes from six to eight. He thought the average was about four per day over the period for two men. The men carried a copy of the circular-letter, and wore a uniform hat, as well as having their maintenance bags painted "Sutton Gas Company."

Mr. G. S. Gadsby (Gas Light and Coke Company) declared that the finest advertisement for a gas undertaking was a fully satisfied consumer ; such a consumer could only be obtained by keeping all appliances in a state of efficiency, by the aid of skilled periodical maintenance. Apart from cost, of course, one of the great difficulties in connection with maintenance was the equalization of the labour load throughout the year.

Mr. W. R. Moger (Tottenham) : Do your two men go together, or do they work separately? Is each job a man goes to on a particular day done on that day? If not, there must be considerable waste of time.

Mr. Davis did not think there was any waste. As explained in the paper, about one day was allowed to elapse after the sending of the letter, and then the fitter called and did the work. Sending a man beforehand would increase the cost.

Mr. Moger said that such a man would do minor things, but report back material required to the second man who was coming along. He himself would regard from two to four jobs a day as being rather low.

Mr. Davis : The men are going to houses that have been unattended to during the war. Later on we shall hope to do more.

Mr. Moger : I think if a man went forward and reported material required, it would help considerably.

Mr. Davis : The houses so far attended to have mostly many appliances in them.

The Chairman said he regretted the unavoidable absence of both Mr. Creasy and Mr. Becket. Referring to prepayment installations' inspection, he stated that his Company accepted special responsibility in connection with automatic supplies, and were doing this work very thoroughly. They had already got through some two-thirds of it. They were now sending out about 7000 lighting fittings weekly, for replacing obsolete patterns. So far as the ordinary consumer was concerned, the Company's work began really in 1907, when the Special Service Section, which Mr. Creasy so ably directed, started giving particular attention to doctors, architects, and similar professional men ; and in 1914 they commenced to deal in the same sort of way with the industrial consumers. In 1921 they started a thorough examination of the whole of the ordinary supplies. He would ask Mr. Ardley, who was connected with this branch of work, to give the meeting some particulars of what was being done. It had been urged in the course of the discussion that lighting burners should be maintained once a month. This, however, appeared to him (the Chairman) a little difficult, on the ground of cost. Judging from his own experience of the cost of thoroughly examining and putting in good order a lighting burner, he would say that if they were to do this free twelve times a year, the whole of the profit on the gas consumed through the fitting would be more than absorbed. This would, of course, make the maintenance of lighting burners free an impossibility. Generally speaking, prepayment consumers could be relied upon to look after their burners, if they were given good ones ; and they could be inspected at much less frequent intervals than once a month.

Mr. R. P. Ardley (Gas Light and Coke Company) agreed that there was a good deal of looseness in the use of the word "maintenance." Often what was meant was inspection, which was a different thing altogether. His Company early recognized that it did pay to undertake a certain amount of free inspection, of a limited number of appliances at least. It might be possible one day to do it for all consumers ; but at the start they did it for special classes—professional men who came in contact to a large extent with the public, and by whom public opinion was led. The final upshot of this was that, having been found to pay, it was decided to extend the plan to as many as possible of the ordinary consumers. They tried it on one district, to see how it would go, and the results, after about eight months' work were so satisfactory in all respects, that it was immediately put into operation in fourteen dis-

Reduce your Maintenance

tricts; and since then it had been extended still further, to 52 districts in all. They adopted a letter on the lines of that alluded to by Mr. Davis in his paper, and found some such plan was necessary to secure entrance to premises in all cases. In fact, they even went so far as to put the representative's name on the letter itself. It would be rather useful to set-up some definite plan for costing these things. Of course, the first object of his Company was service to the consumer.

Mr. L. RENDELL (Gas Light and Coke Company) remarked that the author quoted 3s. 1d. per consumer as the cost, and said the average number of jobs was about four a day, carried out by two men. This would be 12s. a day, to be spread over two men and material.

Mr. DAVIS pointed out that the men now employed were young men trained in the shops, who were not yet getting the full rate of wage. They were thoroughly trained, and as they went on it was hoped to increase their money.

Mr. E. L. OUGHTON (South Suburban Gas Company) said that in 1912, when he was in Yorkshire, they had a free maintenance system —free labour, but the full showroom price charged for all articles sold. In order to attack a problem like this successfully, they must be whole-hearted; and therefore he was glad to see "all" the gas apparatus mentioned in the paper. Maintenance demanded the very best man possible. He should be skilful in his adjustments, and in explaining to consumers the ins-and-outs of the appliances. When this was the case, one could lengthen the period between maintenance visits. If gas undertakings did not keep in contact with their customers, they would lose business; but with efficient men, who would tell the consumers how to reduce their gas consumption within proper limits, they would make friends. He wondered sometimes whether it would not pay large undertakings to charge the net cost of appliances, *plus* overhead charges. Inspecting the main cock and meter was most important, and so was attention to ball-and-socket joints. He did not think the labour charges, for a first inspection after a long period, could be regarded as very high, because it seemed that a really good job had been made of it; and as the scheme went on, the costs would be materially reduced. At the same time, a man who had to represent a gas company in this way was entitled to the best remuneration for his services.

Mr. DAVIS said that for material used on maintenance they also charged full showroom prices, which they regarded as reasonable. The maintenance scheme had caused them to scrap a large amount of apparatus — including cookers.

Mr. F. PICKERING (Rochester) said his Company had had burner maintenance in operation for a few years, and there were now some fifteen men who did nothing but clean incandescent burners and glassware. In private houses all the burners were attended to once a month, shops fortnightly, and in a few odd cases weekly. There were a very large number of outside lamps; and the Company were particularly keen on keeping them in good condition. They were careful to polish the tops, which was important. Labour was given free, and materials were charged for at ordinary showroom selling prices. Three years ago they started on a census; the men doing nothing more than take information. It was found that they could do fairly thoroughly from thirty to forty houses a day. Following on this, they started to maintain gas fires and other apparatus. With regard to cookers, they had not yet a complete maintenance scheme, but he hoped that shortly it would be in operation. The best man that could be got for the work was none too good.

Mr. DAVIS said his Company had a scheme of this kind for outside lamps, which was very successful. They cleaned them once a week.

The CHAIRMAN pointed out that with certain classes of apparatus care should be taken that the gas consumption was limited to that which was most suitable to the appliance. It seemed to him that the question they had been discussing bore upon hire and hire-purchase. If gas undertakings were going to be responsible for appliances, it was certainly desirable that they should be able to scrap them when they became obsolete. Hire and hire-purchase should be limited to the very best class of appliances, and should be applied only to houses the occupiers of which were likely to look after them. He suggested that it would be well if they could get together and see how hire rates were arrived at. They varied enormously for the same apparatus in different districts. Did Mr. Davis's hire rates provide a margin for work of this kind?

Mr. GAGE replied that for cookers or other appliances they took as a general rule the total cost of the apparatus, and charged for hire about 10 p.ct. per annum on this. It paid them fairly well.

The CHAIRMAN said this appeared to him extremely small, unless one was putting in apparatus which it was considered would not become obsolete, and would last for (say) twenty years. In the past, of course, much apparatus had been taken out because it had become obsolete. They wanted a margin sufficient to enable them to do free maintenance.

Mr. J. C. WALKER remarked that they were more or less agreed that maintenance was a necessity, if business was not to be lost. After they had gone to the trouble of persuading a consumer to let their representative have the run of his house, they should certainly utilize this opportunity for securing new business, wherever possible; and therefore the men employed on the work should be of a good type, with some experience of salesmanship. It should be one of the functions of the gas company and of their representative to encourage consumers to complain when they had cause for complaint. They should be continually telling the consumers what they were prepared to do for them. It would be interesting to know whether there was any record of the influence of maintenance on consumption.

Before the meeting separated, Mr. Davis was, on the proposition of the CHAIRMAN, heartily thanked for his paper.

West Riding of Yorkshire Circle.

A Meeting of the Circle took place on May 13.

Prior to the business meeting the visitors were entertained at tea by the Elland-cum-Greetland Gas Company, following which the business proceedings were presided over by Mr. S. H. PACKER, Chairman of the Circle.

The CHAIRMAN said the members were glad to come to Elland, because it meant renewal of acquaintanceship with Mr. Bridge, who had opened their session with a paper at Bradford.

Mr. J. W. H. Fox, Vice-Chairman of the Company, offered a cordial welcome to the members, and extended the apologies of the Chairman of the Company (Mr. W. E. Dyson) for his unavoidable absence.

Mr. J. BRIDGE, Engineer and General Manager, added a brief welcome.

SALES AND SERVICE OF THE SMALL UNDERTAKING.

By J. W. HOLROYD, of Elland.

The large undertaking can employ specialists as salesmen whose activities are solely confined to this work. This, however, is not possible in the smaller-sized concerns; and in Elland, the salesmen are the distribution superintendent, the collector, the showroom clerk, and all men on district, who are really potential salesmen.

The distribution superintendent is responsible to the Engineer and General Manager for all work connected with the undertaking from the gas leaving the works to the point of utilization, excepting collection, stating, and clerical work therewith. In addition, it is his duty to canvass the district, calling on industrial, as well as domestic, consumers. At the time of the canvass or other interview, the consumer is advised of the apparatus most suitable for his particular needs. If an order is obtained, particulars are taken of the material required to execute the work. It is therefore of great importance that the practical training of such a man should be as good as his theoretical knowledge. By the policy adopted we obtain a closer personal touch with the prospective buyer. He clearly sees that his requirements are receiving attention by the chief officials of the Company, and, knowing this, realizes that any promises given, or statements made as to the cost of the work and when same can be carried out, will not lead to disappointment. Such an understanding invariably clinches a sale, while an evasive reply of "within a day or so" might lose the order. The distribution superintendent supervises all main and service laying, and is responsible for the recording of this work on the Ordnance maps and in the books. He is consequently familiar with the conditions prevailing in the district while carrying out any canvass, and is favourably placed to diagnose any trouble occurring as to insufficiency of supply, &c., caused by overloading of mains and services. It is also his duty to get the fitters out to work every morning, having prepared their lists of work over-night, and also to visit these men during some part of the day, to inspect their work while it is in progress. The work and time sheets of the previous day are prepared for the Engineer and General Manager's inspection before 9.0 a.m.; and thus we are able to keep closely in touch with the actual working hours of each man, his unproductive time, and, generally, his value to the Company. The smaller undertakings certainly can give more personal attention to the consumers; and our work at Elland has given rise to good feeling. The consumers appreciate that, if they want a job done well, the Gas Company can do it.

In our undertaking the collector is a man of good education, and, having been connected with the distribution department for many years, is to us a salesman of no mean order. The collector has splendid opportunities of doing business or paving the way for business. On many occasions it has been found that orders received are the result of information and advice given by the collector while carrying out his duties. Besides delivering accounts and receiving payment for them, he receives any complaints from the consumers; and his timely reports and advice prevent dissatisfaction.

The showroom clerk is an understudy to the distribution superintendent. He has had practical experience on the district with the gasfitters and maintenance staff.

Even the smallest undertaking should have a showroom; but in a scattered district like ours, it is not as beneficial as we should like it to be, there being many consumers in the out districts who never come to Elland. You will readily understand this when I point out that three of our outlying villages, representing practically 50 p.ct. of our sales, are in direct communication with either Halifax or Huddersfield by tram and 'bus, and in consequence shopping is done at the larger towns. Our present showrooms are rented premises, situated in one of the main streets of Elland. They have a good frontage, allowing a neat window display; but the interior is unfortunately very small, and does not allow enough room for a representative show. However, in the near future we hope to erect showrooms on a plot of land recently purchased in the main shopping thoroughfare of Elland. During the recent lighting season, we made a special feature of lighting the exterior of the showrooms by 3700 c.p. lamps, and at the same time started a campaign for outside shop light-

ng. Our own display had the desired ffect, and easily converted shopkeepers to he scheme. The scheme is to supply on imple hire 700 c.p. lamps, fixed free, at rental of 30s. per annum—10s. per uarter for the two winter quarters, and s. per quarter during the two summer uarters. The agreement is for 3 years. Our total for the first season was 21; and ve feel sure this number will be considerbly increased in the near future. Our howroom window is re-dressed at least nce a fortnight; and the display is made o coincide with the advertisements apearing in the local Press.

Besides advertising in the local "Adverliser," which has a circulation of 4000 opies each month, we have a full page in ach of the different Church magazines, nd the "Free Church Journal," which ave a circulation of over 1200 each nonth. With every gas account we send ut small seasonable advertisements, and t times make use of the well-known 'B.C.G.A." stamps. Where any accounts re sent through the post, we utilize the llustrated envelope, so that every availble source of local advertising is in constant use. We have no doubt that this ays. We must keep our goods before the ublic; and the way to do it is to give hese goods the publicity they merit.

Our undertakings are known as public ervice undertakings. Let us live up to his name, and give that quality of service vhich in the future will stamp our inlustry as a key industry. To attain this uality of service in the highest degree is he aim of my Chief. For the past six nonths the distribution superintendent, in conjunction with the Engineer, has given morning talks two mornings per week to ll members of the service staff. Those alks have already covered a wide field; nd it is intended that they should deal vith the whole subject of service. In order to get the best out of each man, it is necessary to give even the humblest and he youngest an opportunity of knowing as much as possible about his business nd the policy of the undertaking.

The aims of a gas service department hould be such that:

1. Orders are executed promptly and fficiently, to the satisfaction of the conumer. A consumer must not, and will ot, be neglected. He must have the best f attention, or we must expect to lose im. This is so obvious that some may e tempted to doubt the necessity of tating it; but there is no denying that lack conditions still prevail in many ndertakings.

2. That information of a reliable nature eaches the superintendent from the disrict relative to complaints and the general eeling of the consumers to the underaking.

3. The staff are properly trained and vork in harmony. Loyalty of the staff is est obtained by the attention which is hown by the chief.

4. Only approved goods are stocked, nd these sold at a reasonable figure, so hat we may protect the consumer from hoddy goods.

5. We are ever in the minds' eye of preent and prospective consumers. Make hem feel that their personal interests and omforts are being studied, and that, if a ob has to be done well, the gas company re the people to do it.

It is well to remember that the public udge the quality of the gas by the results hey obtain with their appliances. In the nterests of service we must examine eriodically each appliance on the district, o see that it is giving the highest effiiency. Hence the necessity for an organzed maintenance scheme. We have a cheme in operation employing four specilly-trained men. They have just comleted a round of the whole district. For he first visit an entrance to each conumer's house was gained by presenting a folder expounding the scheme, having a detachable back leaf in the form of an agreement, requesting the Company to clean a specified number of burners periodically. The fact that 2000 of these agreements have already been signed and returned to the Company proves that the consumer does appreciate service. The folder and form only state incandescent burners. However, we had no intention of confining our activities to lighting alone; and once in the house, we take the opportunity of inspecting, overhauling, and maintaining every piece of gas-consuming apparatus, whether or not it is owned by the Company.

We have a special gas-fire maintenance scheme, by which all consumers' fires are cleaned and adjusted three times during the winter season. Despite the poor trade in the town, where some of the mills are closed and others working restricted hours, our maintenance men have helped to increase the sales to a great extent, especially in the lighting field. They have introduced up-to-date fittings and burners in place of old ones; and it is a remarkable fact that the introduction of one burner has in several cases been the means of a request to light the whole building. At this point it would perhaps be of interest to mention a few of the larger sales we have negotiated this last season:

Three churches re-lighted, introducing distance control.

A sanitary pipe works re-lighted with 35 "Littleton" lamps of various sizes, 21 of which are on separate distance controls.

A factory re-lighted with 89 factory lights.

In addition, we have been fixing cookers, fires, and boilers at a rate of not less than one per day—and this in a district where coal is cheap and easy to obtain.

Arrangements are in hand for an exhibition to be held in September or October. It is a debatable question what part of the year is most suitable for a small undertaking to hold an exhibition. Gas is now so widely used that every day is a gas day. After consideration, we have decided that the commencement of the gas-fire season will be the best, for the reason that we then get two main lines that are seasonable—fires and lighting. We shall therefore have a special fire and lighting display, but shall not by any means neglect the cooker display, which will be augmented by a series of cooking demonstrations and lectures. Here again the difficulty of a scattered district arises, but my Chief suggests engaging chars-a-bancs, and running to the outlying districts a free service to and from the exhibition, and concentrating the whole of the exhibition in Elland, which represents 50 p.ct. of our sales. By this means we shall do better than by holding small exhibitions in each of the outside villages we supply.

In conclusion let me quote a paragraph which I remember reading a good number of years ago: "You can buy in your armchair, you can keep accounts on a stool; but to sell, you must get up, and get out, and get busy." To my mind, this paragraph sums up the whole business of salesmanship, and is particularly applicable to our policy—we do get out, and we are kept busy.

Discussion.

Mr. F. Lodge (Wakefield), after congratulating Mr. Holroyd on his paper, said he was impressed by the excellent suggestion that collectors should be salesmen. In some cases collectors did not act in this way as well as they might do; and yet there was no man who came into more direct contact with the consumer. The idea of free transport of people from outlying districts to the proposed exhibition was new; and he hoped it would be a great success. He was interested to hear of the maintenance scheme, and particularly the cleaning of fires three times per year.

Mr. H. Rhodes (Bradford) believed in the possibilities of utilizing distribution men as salesmen. He would like to ask what system Elland adopted in regard to the meter difficulty. In Bradford, though the undertaking had taken over a good many meters, a large proportion of domestic meters were owned by the landlord. Many of them were not big enough for the work demanded, but the owners were not willing to instal new ones.

Mr. M. M'Kennerney (Keighley) asked why Mr. Holroyd favoured exterior lighting for shop windows, as compared with inside lighting. Did the collectors at Elland receive a bonus for the orders they obtained?

Mr. J. W. Lupton (Otley) asked whether Mr. Holroyd's maintenance scheme was free. In Otley the people greatly appreciated free maintenance service.

Mr. C. Watson (York) said Mr. Holroyd's paper, though devoted especially to smaller undertakings, was equally applicable to large concerns. There were certain phases of effort which the small undertaking could develop very readily, and from which larger concerns could learn a good deal; and he thought it was good policy for the Circle to have many of their meetings in the smaller towns. He thoroughly endorsed all that Mr. Holroyd said as to good feeling throughout the staff. He thought that high-pressure exterior lighting, while good for public squares, &c., was not the best for shop windows. On the other hand, with indoor lighting there was a liability to steamy windows, unless there was very good ventilation. He thought an excellent indoor window lighting scheme was by superheated burners with six or eight mantles.

Mr. L. Denham (Halifax) said that in Halifax they were keen on high-pressure lighting.

Mr. Lupton, referring to Mr. Holroyd's question as to the most suitable period for a gas exhibition, suggested the early summer, when the cooker demand was strongest.

Mr. Bailey (Cleckheaton) remarked that much success was to be achieved by creating, through education of staff, good gas workmanship. He thought the ideal shop window lighting was exterior, because it attracted people from a distance.

Mr. H. Sykes (Bradford) asked Mr. Holroyd if he gave local plumbers any special encouragement for co-operative working with the gas undertaking. In some municipalities, said Mr. Sykes, the collectors were responsible for gas, electricity, and rates accounts; and he knew of their taking round electricity pamphlets while collecting gas accounts. Did the morning talks at Elland clash in any way with Institution classes in the district.

Mr. Denham said he noticed Mr. Holroyd told his consumers the undertaking would be glad to examine appliances on application. Would it not be advisable to call and examine before application?

Mr. J. R. Firth (Bradford) asked whether it was possible for Mr. Holroyd to give the figures for the last six months of cost of the maintenance service. What means had he of ascertaining the walking time expended by the men, and what was the average of burners per man per day?

Mr. Adamson (York) corroborated the view that outside shop window lighting was most valuable in attracting business.

Mr. J. H. Pickles (Halifax) said another important factor of the value of exterior shop window lighting was that the natural light of day was from the outside; and artificial light should approximate as nearly as possible to daylight conditions. He thought outside lighting added probably 50 p.ct. to the selling appearance of the goods in the window.

Mr. Adamson agreed with Mr. Pickles, and pointed out that the normal window was dressed for daylight.

Mr. M'Kennerney remarked that inside lighting was inexpensive, and could be made most artistic.

Mr. Fletcher (Wakefield) said he had been impressed by the idea of free transport for outdistrict people to the proposed exhibition. Mr. A. E. Mottram, of Ossett, in his recent paper in that town, had suggested taking gas appliances round on a lorry to show to people who would not come to the showroom.

Mr. Watson said there was a good deal to be said for the idea of taking goods to the people, even if it meant holding district exhibitions or opening branch showrooms.

The Chairman (Mr. Packer) said Mr. Holroyd's paper had indicated the enthusiasm, harmony, and efficiency which prevailed throughout the Elland Gas Company's staff.

The first part of the paper seemed to him to bring out a great, but often forgotten, principle —that the whole of the business world rested on confidence. Ignorance was the great cause of lack of confidence; and the way to cure this ignorance was by publicity by way of the showroom and advertisement. Elland was giving a lead to many larger undertakings in the way of local advertisement. When had they heard before of a small undertaking giving regular morning talks to the men? This was one of the most striking points in the whole paper. It was evident from the paper that members of the Elland staff were made familiar with the policy of the undertaking. There was no better tonic for sick sales than systematic staff training, because it made the salespeople interested in what they were doing and selling.

Mr. Bridge congratulated Mr. Holroyd on the paper. Mr. Holroyd was a most valuable member of his staff. The paper was a new departure in that it dealt to some extent with the policy of the undertaking. He thought it was a useful departure, particularly in view of the fact that the efforts of the Circle had been specially concentrated during the past season on behalf of smaller undertakings. Salesmen, as such, were not responsible for the policy of their undertakings, but there was no reason why they should not discuss policy. The maintenance schemes and the education of the gas service men—he liked to call them all by the title "gas service men" and make them all feel that they had an important part in that service—were valuable in enabling all salesmen to study the policy of the undertakings with which they were concerned, and the policy of the undertakings in their district. Mr. Bridge said there was no monopoly of brains in one man in any undertaking; and he gained much valuable help and information from his salesmen and his gas service men generally. At the opening of the session of the Circle he had given a paper in which he had made some suggestions; and he would venture now to make another. The Circle had members who were responsible for many duties in distribution and utilization of gas; and he would urge that they should get a little more from the beaten track, and discuss the policy of gas undertakings. He felt that something very useful would be the outcome. Good service, added Mr. Bridge, warranted good pay. It was a well-known fact that in the gas industry it was easier to fill a vacancy on the engineering or mechanical side with a thoroughly suitable and qualified man than it was on the distribution side. It was up to such organizations as the Circle to prevent this situation existing much longer. Mr. Bridge went on to suggest that, while the industry had no desire to place men "on the shelf" because they were getting older, it was desirable that all undertakings should make schemes of provision for men from the age of (say) 60 years, so that the younger men could have a chance.

Mr. Holroyd, replying to the discussion, said that, in regard to shop-window lighting, the steaming of the window by inside lighting, unless there was good ventilation, was against such lighting. Then again, there was the attraction of people to the shop by outside lights. Mr. Lupton had questioned the period of the proposed exhibition. He thought they would not lose much cooker business because, as Mr. Packer had said, it was now fairly even throughout the year, in addition to which they were going to make a special display of cooker service, in addi ion to lighting, fires, &c. The maintenance scheme was free. The offer to call and examine "on application," was a request to consumers with whom they were already in touch. It was a request. They did not believe in forcing anything down the public throat. In answer to Mr. Sykes, the Elland undertaking worked harmoniously with the local plumbers. One of the latter was at present making a special show of a gas cooker and two fires loaned for the purpose by the Company. The morning talks did not in any way clash with the Institution classes. As to the walking time of the men, this was checked by the time sheets, which recorded the times of starting and finishing every job. They had to trust to the honesty of the men's records. A knowledge of the district was, of course, an excellent check. In regard to the average of burners cleaned per man per day, it varied according to whether the houses were scattered or close together; but a rough average time was twelve minutes per burner. Mr. Rhodes had raised a question as to house meters. This certainly was one of the difficulties of satisfactory gas service. Wherever possible the Gas Company had suitable meters in the houses. Most of them were owned by tenants rather than by landlords.

On the motion of Mr. C. Watson (York), seconded by Mr. D. Parsons (Huddersfield), a hearty vote of thanks was awarded the Chairman, Vice-Chairman, and Directors of the Elland-cum-Greetland Gas Company, and to Mr. Bridge, for their hospitality. Mr. Fox briefly responded.

On the motion of Mr. L. Denham (Halifax), seconded by Mr. Adamson (York), Mr. Holroyd was warmly thanked for his paper.

It was announced that the next gathering of the Circle would be an all-day visit, on June 10, jointly with the Manchester District Circle, to the works of Messrs. Wilsons and Mathiesons, Leeds.

Lancashire District—Manchester Section.

In last month's "Salesman" (p. 93) a brief account of the April meeting of the Circle—at which Mr. Sillitoe, the Chairman, presided—was given. We now publish the papers read at that meeting, and the discussion to which one of them gave rise.

NOTES ON GAS LIGHTING.

By W. B. Payne, of Liverpool.

The competition to-day between gas lighting and electricity is very keen indeed, and we, as gas salesmen, must be in a position to put forward the best possible case for the commodity we are selling. To do this, we must have a thorough knowledge of the most efficient appliances on the market.

Internal fittings should be compact and neat. Solid-drawn tubes only should be used, while all ball joints should be well ground-in and sprung. It is also of importance that all swivels and taps should have a good body of metal.

Each gas undertaking, by making tests, ought to find out the most suitable burners for the gas supplied, and standardize them as far as possible. Cheap burners must be avoided at all costs, for while they often look good, examination soon lays bare the defects. They are not scientifically made, and, as a rule, have a stamped or badly-drilled nipple, a metal nozzle of the same diameter throughout, and are fitted with an iron-wire gauze. The really good burner should have a machined and properly-drilled nipple, otherwise the stream of gas will be deflected towards the side of the mixing chamber, and the efficiency of the burner will be impaired. Owing to their non-conducting propensities, clay nozzles are undoubtedly the best. Lugs or deflectors should be fixed to prevent the products of combustion entering the mixing chamber a second time. The hottest part of the flame being just inside the outer envelope emphasizes the necessity for always using a properly-shaped mantle, the fabric of which ought to be of either ramie thread or artificial silk. Cheap mantles, as a rule, are very badly shaped, and the wise course is to avoid them.

A flame of high temperature can be better obtained by burners of the superheated type screwed into a chamber with a large surface over the heating points. The temperature of the gas and air mixture is thus raised while passing through this chamber. The efficiency of superheated burners is shown by the fact that a cluster of three bijou mantles will give almost twice as much light as a No. 3 standard burner at the same consumption. A further advantage is that, small mantles being stronger than large ones, maintenance costs are brought much lower. In the event of one mantle being broken, there is still left a considerable amount of light.

It may be well to consider here the consumption and illuminating qualities of good inverted burners. The No. 1, or bijou, type consumes approximately 1½ c.ft. per hour, the No. 2 burner 2½ c.ft., and the No. 3 burner 4 c.ft. per hour. The average candle-power per c.ft. is from 18 to 20. Mantles of a larger size than No. 3 should be abolished in favour of cluster burners.

Globes play a very important part in good lighting. Avoid those that are heavily frosted, using only the clear or lightly-frosted types. There is a loss of only 5 p.ct. of light when a clear globe is used, but when coloured ones are in use the loss rises as high as 50 p.ct. The Vitreosil globe answers very well. It is neat in appearance, close to the mantle, and is unaffected by the heat. Another very good globe, though not fireproof, is the Supastone, which is larger and gives better all-round duty.

In dealing with domestic lighting, the colour of the decorations and furniture must be considered. Anything of a dark nature absorbs light; and if these conditions are in existence, provision must be made accordingly. It is generally understood that, for house lighting, 3 to 4 foot-candles over the whole area is adequate. Burners of the direct lighting type should be used on brackets round a room, while for centre lighting those of the semi-indirect type are very good. While the latter method entails a slightly larger gas consumption, the results are more pleasing; and all forms of glare are eliminated. Burners of the by-pass pattern should always be fitted on landings, also in the halls and bathrooms. The switch should be remembered; the pneumatic system being the simplest.

Shop lighting, both inside and outside, requires careful attention. The arrangement of the trading goods, as well as the showcases, must be taken into consideration. A great mistake, and one often made, is to try to illuminate a shop by using the old lighting points. A drop fitting is usually placed over each counter, and one or two in the windows. Lamps of high power are fixed at these points, with the inevitable result that under the lamps a brilliant light is obtained, while the remainder of the premises is left in semi-gloom. We should aim for a light duty of from 4 to 6 foot-candles over the whole floor-space. It is infinitely better to put in new lighting points, and to use a larger number of smaller lighting units to equalize the amount of light over the whole area. For outside window lighting the conditions are somewhat different. The shopkeeper usually desires a blaze of light, not only to illuminate the window, but also to attract attention to his premises. Cluster lamps such as the "Littleton" or similar types can safely be used for this purpose. Their polished copper bodies, enamelled reflectors, superheaters, and neat design all combine to lend an attractive appearance; and the lamps give excellent duty. They are easily cleaned and regulated, and can be obtained with any desired number of mantles up to 15. As an advertising medium they are admirable, while, if required to illuminate a window display, they can be fitted with parabolic reflectors. By-pass levers and chains are usually fitted to these lamps; but if desired they may be controlled by a distant-control device made by Messrs. Sugg, and operated from inside the shop.

In dealing with factory lighting, a 3 to 4 foot-candle duty should be aimed at over the whole area to be lighted. Nothing causes eyestrain quicker than a brilliant light in one part and dark shadows in another; and where industries have to be carried on by means of artificial light, production is impaired if such light is not evenly distributed. Good general lighting tends to make the worker cheerful; and this condition undoubtedly makes for increased production. The danger from machinery in motion in badly-lit workshops and factories is obvious. Overhead lighting is best for this purpose, and can be accomplished by cluster lamps fitted with enamelled reflectors. They should be nicely spaced, and may be controlled by the distance-control device mentioned before, or, if preferred, by-pass levers and chains could be fitted. Anti-vibrators can also be attached for the purpose of absorbing any shocks set up by the operations in progress. In addition to the general lighting, smaller units may be fitted for special purposes such as cylinder boring, planing, or drilling. They should be of the movable type, and fitted with parabolic reflectors to change the direction of the light when required.

Street lighting by gas is more than holding its own; and I think that it is a generally accepted fact that in foggy weather no other form of lighting has the same powers of penetration. In busy thoroughfares the distance between the columns should be 40 yards, while in the suburban areas 50 yards is ample. Here again I am in favour of the cluster burner, both from the illuminating standpoint and from that of maintenance. At street corners and in busy thoroughfares, the "Littleton" lamps, fitted in the ornamental harp supplied by the makers to suit existing columns, give excellent duty.

The question of high-pressure gas for street lighting is also worthy of serious consideration. London, Manchester, and Birmingham have fine examples of this form of lighting. Generally speaking, when gas is compressed to 80 in. water-column, or approximately 3 lbs. pressure, it gives the best duty. Each lamp should be fitted with a by-pass. Lamps can also be arranged in groups of twelve, operated by a control governor. If a compressor is used for street lighting only, it can be fitted with a special loading device which increases or decreases the pressure at will, and enables all the lamps on the district to be lighted or extinguished at one time.

The salesman has something more to do than sell an attractive fitting or lamp. If only a replacement is required, a few judicious questions will soon discover what is the best article for the job. If a new lighting scheme is in contemplation, suitable fittings may be shown and prices quoted, but a visit to the premises by the outside representative is advisable in the interests of all concerned. There are places where electric lighting is more suitable than gas, not from an illuminating standpoint, but purely from the point of view of expediency and convenience. Generally speaking, gas lighting can more than hold its own. It is of the right colour, eyestrain is avoided, ventilation is improved. Moreover, illumination by gas is economical. These conditions only apply, however, when the burners are giving their highest duty; and I regret to say that unfortunately the opposite conditions are far too often the case. In many instances the best possible burners are fixed, but with indifferent results. Gas, fortunately, is a good servant, and will burn under almost any conditions; but dust drawn into the burner, deposit from the products of combustion, and dirty globes all combine to handicap it from doing its best. Undoubtedly the remedy for this is maintenance. Much has been said on this question of late, but Glasgow has been the only undertaking to put it seriously into operation—that is to say, as a direct charge on the gas. The cost, I believe, is just over 1d. per 1000 c.ft. of gas sold, and the results are satisfactory. The latest figure for Glasgow maintenance is 0·529d. per 1000 c.ft.

Free maintenance must of necessity have its drawbacks, for the reason that anything free is always open to abuse. Again, the consumer who does not use gas for lighting purposes has to pay his proportion of the cost. Another scheme is to charge the consumer bare costs for services rendered, charge the materials used at market prices, and put any profit made into the scheme, and so cheapen it.

A stroll round the shopping centre of any town after lighting-up time will convince anyone of the necessity for maintenance in some form, as, generally speaking, the lights are in a deplorable condition.

A number of the slides, kindly lent by Messrs. W. Sugg & Co., of Westminster, were then thrown on the screen.

Discussion.

Mr. WILLIAMS (Chester) asked Mr. Payne if he would advocate the use of the flexible tube. Mr. PAYNE said he did not.

Mr. BRADBURY (Rochdale) asked whether the pepper-box nozzle was superior to the open type.

Mr. PAYNE said the pepper-box nozzle was largely used at Liverpool. It was their experience that a higher candlepower was obtained by breaking-up the gas and air mixture into a number of streams.

Mr. ROBERTS (Nelson) asked what was the duty of high-pressure gas.

Mr. PAYNE replied that in Liverpool they had obtained 60 c.p. per c.ft.

Mr. COOK (Warrington) asked for information on the cost of the gas switch.

Mr. PAYNE said that the cost of installing gas switches was reasonable. They had no difficulty in persuading customers to fit the pneumatic switch. The majority of people spoiled the working of the valve by applying oil to it.

THE OUTDOOR GAS SALESMAN.

By C. DICKENS, of Manchester.

Of the various forms of propaganda and publicity, all of which are indispensable to the salesman, there is no adequate substitute for the personal interview. I think it is now universally agreed that the gas salesman must be something more than a well-spoken and courteous individual equipped with a smart suit of clothes and a capacity for "telling the tale." My own experience is that what usually faces the salesman is not so much the all-important question of recommending the right apparatus, but the problem of installing the appliance (under what are very often adverse conditions) in a satisfactory manner, and with an eye upon the subsequent question of maintenance.

Manchester, in common with other undertakings, has always considered outdoor salesmanship to be a practical man's job. By this I mean that the salesman must be sufficiently experienced on the practical side to be able to instal efficiently an appliance he has recommended. It is obvious that, if the salesman is not competent in these respects, he may be creating future trouble for his undertaking, and may also be preparing a rod for his own back.

A method in operation in Manchester, while not being put forward as an ideal, has many advantages. The sales and maintenance departments are combined; and all apparatus installed automatically comes under the maintenance service. The outdoor salesmen (who are classified as district inspectors) are allotted districts, of which they are in complete control in their own particular branch. The duties include not only the selling of apparatus, but also the responsibility of maintenance. The district inspectors or salesmen are equipped with the necessary literature and application forms, &c., and are encouraged to promote sales. I think I am right when I say that nothing is more fatal to a prospective sale than to have to inform a consumer that he will have to call at the showrooms to make an advance payment, or sign a form, or that another individual will have to call to inspect and measure-up, &c. Under the Manchester system the whole of such preliminary work can be completed in the first instance on the job, and arrangements can be made to proceed with the work without further delay. Orders taken are made out in detail on triplicate forms, one of which is handed to the consumer. Upon his return to headquarters, the inspector draws up a complete specification of the materials required for the job, for the information of the fitter. During its progress the work is usually visited by the inspector, who is often at this stage (and also upon his final visit) able to pick up additional work. Upon the completion of the installation, the fitter returns his note, with full particulars of all materials and apparatus fixed, times, fares, &c., recorded on the back. This is carefully checked by the inspector on his final visit, when he tests the installation; and a maintenance card is then issued for periodical attention. Under this system the risks of misrepresentation and unsatisfactory workmanship are reduced to a minimum, and the percentage of disputed accounts is very small.

In circularizing for canvassing purposes, any literature is sent by post enclosed in a sealed envelope, with a covering letter drawing the consumer's attention to an impending visit from the maintenance inspector, who has been instructed to investigate and rectify any complaints, and explain the department's varied services. By this method the salesman gains an interview with a large majority of the consumers; and a number of complaints are usually brought to light. The patient investigation of an apparently frivolous complaint, and its subsequent correction, resulting in the bringing-back into more frequent use of any type of appliance, form, to my mind, a more valuable "sale" than the installation of a similar apparatus for a new consumer. When one calculates the large capital outlay on mains, services, meters, &c., and the standing charges for upkeep, the loss of a consumer, or even a reduced consumption, is a very serious matter; and while new business must be intensively cultivated at all times, it is my firm opinion that it would be a most unbusinesslike policy to neglect old consumers, and lay out further capital in creating new ones.

Many of us were no doubt interested, some little time ago, in an item in the Technical Press announcing a proposed scheme for the education of gas salesmen. I think the proposal was for the formation of a salesmen's course, candidates for which must first qualify by passing for a first-class certificate in Gas Supply, which would enable them to sit for a Diploma of Commerce.

To me the suggested scheme appears to be open to several criticisms. First, it is a well known fact that an expert technician is seldom a good salesman. Secondly, if the proposed Diploma of Commerce provides the degree of commercial knowledge that it should stand for, then there is no doubt that a recipient may find a more profitable avenue for his activities than in the gas industry. Third, I do not think the syllabus in Gas Supply provides for the practical side of gas salesmanship.

The alternatives I have to suggest are: That Gas Fitting be substituted for Gas Supply as a qualification to sit for the proposed Diploma, or, better still, that salesmanship be included in the syllabus of all gas subjects (both practical and theory), particularly in the earlier grades, and in this way, dovetail the technical and commercial sides of the industry. Those who are fortunate enough to be able to digest both lines of thought should then provide the industry with what may be an ideal type of outdoor gas salesman.

Southern District—Sub-Section "A."

April Meeting.

A Meeting of the Circle was held at the "Rendezvous" Restaurant, Woking, on April 6—Mr. F. A. Ricketts presiding.

COOKERS.

By A. W. Cullington, of the Woking District Gas Company.

The cooker is undoubtedly the appliance with the largest sale, and has truly come into its own. In fact, the great majority of housewives to-day look upon the gas cooker as a necessity. As a saver of labour it has no equal. The low price of gas as a cooking agent solves in no small way the financial problem of the housewife.

The cost is doubtless the deciding factor with the majority of people; and in this respect the gas cooker more than holds its own. An average electric cooker costs about 50 p.ct. more than any first-class gas cooker. The maintenance costs of the former are equally high. The elements are very fragile and susceptible to breakage by foods boiling over, &c. Costly in themselves, they are equally expensive to replace. Some electric cookers are now fitted with solid tops to the hotplate, so as to protect the elements. This reduces the efficiency. It is a recognized fact, even among electricians, that the contact type is much more efficient.

Mr. Cullington then dealt with the question of shrinkage of meat in the cooking process, pointing out that the argument often put forward by electricians to the effect that more shrinkage occurred when cooking was done by gas was unfounded. As to the cooker itself, continued the author, this must have a high thermal efficiency and must be hygienic and well constructed. Hospitals should be fitted with the open-type bars, to minimize loss of heat by conduction. Considering the matter of "smothering," Mr. Cullington said that this phenomenon was most noticeable with burners placed near the cornice, where the products were unable to escape freely from under the utensil.

Most flues are made to discharge their products horizontally, with the result that, when fixed near a wall, the latter becomes a trap for the escaping gases. Moreover, in such a position, it is an easy matter for a cloth to be inadvertently dropped over the outlet. In view of this all flues should be undercut.

Mr. Cullington prefers a cooker with 6-in. legs to one placed on a stand, and considers that it is false economy to sacrifice strength and good workmanship for low first cost.

The Chairman thanked the Woking Gas Company for their hospitality, and Mr. W. H. Eley, the Manager, responded.

A visit to the Company's showrooms terminated the meeting.

May Meeting.

A Meeting was held on May 4 at the showrooms of the Aldershot Gas, Water, and District Lighting Company, under the chairmanship of Mr. F. A. Ricketts, of Aldershot.

GAS SALES—LOOKING AHEAD.

By S. H. Wheble, of Aldershot.

We gas salesmen would do well to reflect for a short time on our future. We know our position to-day. Are we satisfied with the way things are going? No, I am sure we are not. I venture to suggest that every gas salesman—though he may be satisfied that his sales are improving—can but feel that now is the time for extra effort. He must obtain more business; he must look after those new dwellings while the opportunity presents itself; he must increase the consumption per service, &c. I am convinced that in the course of his daily round, he must realize that the next few years are going to be vital ones for the gas industry, because of the strength of the general competition we have to face. We must look ahead, and conduct our fight for business on the right lines.

There is a tremendous field before us for development, particularly in so far as heating is concerned, both for water heating and room-warming. Though all circumstances necessary for the obtaining of all domestic heating by gas are not likely to be brought about immediately, we can undoubtedly look forward to doubling our output in this direction in the near future. Cooking by gas, too, must be developed, and lighting must be retained.

We must bear in mind that our competitors are doing their utmost to capture the business we now hold, and to step in where we have failed. It is a big mistake to under-rate their power, but it is also a big mistake to let them see that we realize the strength of the opposition. The realization of the power of our opponents must be smothered by our enthusiasm; and we must go "all out" to win at every turn. We have to consider the following:

Oil, having largely lost lighting to gas, turned to cooking, and is now making a big effort to recover lost ground in the lighting world with its new incandescent mantle light.

Coal has lost cooking, intermittent heating, and water heating to a varying extent, but is still very popular with a large percentage of householders.

The strongest challenge, however, comes from electricity; and it is this which we have to watch most carefully. It has gained much ground for lighting and power, and is challenging cooking and heating. With this commodity it is all a question of cost, which at present militates against its use.

One of the greatest assets electricity has is the vast amount of support which it derives from a large percentage of the big daily newspapers. I think it is generally agreed that there is but little difference in the cost of gas or electricity if the supply is used for lighting only. Convenience may throw weight in the scales in favour of electricity, but I think gas weighs the scale down with a big thud in its favour when it comes to the question of which is the better light. Incandescent gas-lighting with a modern burner stands supreme as an illuminant. Figures prove that, for cooking and heating, electricity is so much more costly than gas that it is impossible at present for gas to receive any very serious challenge, though it is well known to us all that every effort is being made by the electrical industry with a view to securing a good place in these fields.

Regarding competition in the future, I would like to bring to your notice a few facts on the subject of coal conservation, based on a report to the President of the Institution of Gas Engineers by a Committee consisting of Sir Dugald Clerk, and Profs. Smithells and Cobb.

1. Of the whole of the heat expended on the carbonization of coal, if debited to gas produced, 45 of every 100 units are conveyed to the consumer.
2. Regarding electric stations (year 1919), of every 100 units expended by combustion of coal for generation of electricity, 7·6 units are available for the consumer.
3. For the best gas and electricity undertaking, the figures were: Gas, 53 units of every 100 delivered to consumer; electricity, 12 units of every 100 delivered to consumer.
4. It was anticipated that, if electricity was supplied by super-stations, approximately 18 out of every 100 units would reach the consumer, whereas, with improved practice of coal carbonization, gas would deliver 75 units out of every 100 to the consumer.
5. For heating, excepting temperatures over 1700° C., gas is by far the more economical fuel.
6. For lighting and power production, a comparison of the thermal efficiency of fuel consumption in the case of gas and electricity does not give the dominating claim to either.

Finally, it was strongly urged that maintenance and development of the gas industry is essential in the interests of fuel conservation, if for no other consideration. Surely these are figures and facts full of hope to the gas salesman, even though it is known that electricity can be generated by other means than by the use of coal. The erection of super-stations for the generation of electricity undoubtedly finds support from several aspects; but I venture to suggest that the distribution of supply to the consumer is going to be very costly.

The first aim of every gas salesman should be to get every possible piece of apparatus into dwellings already supplied, to increase the consumption per service. Now is the time to investigate every house, in particular for heating and cooking. It is far easier to turn the weakest competitor out, and become firmly established, than it is to "get in" against strong opposition. Moreover, it is going to weaken the strength of the strong competitor. We all know the difficulty of persuading anyone to scrap (say) an oil stove for a gas cooker which would render them a more satisfactory service. It is a more difficult proposition than offering a gas stove to replace a trying coal range. We must be first in the field, if we wish to reap the maximum amount of success. Every effort should be made to get mains laid in every district where there is a possibility of development, even though at present there is only a small return. I see that these next few years mean almost everything to us, if we, as we undoubtedly do, want to lead in the fuel field.

We must use every effort to put before architects and builders the advantages to be derived from the use of gas. The provision of gas flues to replace chimney breasts is one of the chief items we should press.

All consumers cannot afford to pay cash down, or even hire-purchase terms, for the necessary apparatus. I therefore suggest that, during the next few years, gas companies should supply and fix all types of gas appliances on low quarterly rentals—looking to the revenue derived from additional gas consumption to cover the purchase of the apparatus. Obviously, we shall all do our utmost at all times to obtain payment for apparatus installed, as we realize that the heavier the charges the company has to bear, the higher will be the price of gas. However, it is increased consumption that is most essential to bring about a reduction in price, so that it will obviously be in the best interests of every company to incur some little expenditure, in the provision of mains and apparatus, with this end in view. The appliances employed must, of course, be the most efficient type obtainable; and we must see that every consumer is rendered the best possible service.

Sales and service go hand in hand; and we must bear in mind that it is the gas salesman's duty to see that complaints are promptly attented to, and that apparatus purchased or hired is promptly fixed. One of the greatest assets any undertaking can have is a mass of contented consumers. In this connection it is essential for the sales and distribution departments to work

together. Our organization must be so perfect that every cog in the machine for supplying gas and apparatus to our consumers runs smoothly.

It is essential for our future success that showrooms be provided in which the working of all types of gas apparatus generally in use on the district can be properly demonstrated. Another important matter is that of the education of the consumer. We shall derive much assistance in building-up future sales by educating schoolgirls of to-day in the use of all domestic apparatus; and every opportunity of installing suitable apparatus in school cookery centres, &c., must be taken. The older schoolgirls of to-day will be the young housewives of the time when we shall probably find the strongest competition. If these girls are on our side, we shall find it easier to win through.

Now is the time to lay the sound foundation; and the building-up must proceed with the utmost speed, to enable gas to maintain the lead.

Votes of thanks were passed to Mr. Wheble for his paper, and to the Aldershot Gas, Water, and District Lighting Company for arranging for the meeting.

Midlands Circle.

A Meeting of the Circle was held at the Chamber of Commerce, Birmingham, on May 13—Mr. G. M. LEWIS in the chair.

PUBLICITY AND PROGRESS.

By W. T. PURCELL, of Stoke-on-Trent.

In the commercial world it is agreed that publicity and progress go hand in hand; and it is a fact that many firms who sell well-known commodities depend on publicity for their existence.

In the gas industry the showroom is a constant publicity agent, never resting on the merit of past achievement, but constantly striving to obtain further business. The first duty of the showroom is to demonstrate to the public what gas will do; and to an active and progressive undertaking a showroom is indispensable.

The service rendered by the gas industry affects the health, convenience, and comfort of all classes; but there are still thousands of people prevented, by ignorance alone, from deriving real benefits from the use of gas. It is an obligation of the undertaking, and a duty of the showroom, to enlighten the public on this vital subject; and to indicate by practical demonstration and suggestion what gas will do.

The showroom must be situated in or near the shopping area of the town; for the buying public will not go down a side-street or to a stores at the gas-works to make their purchases.

Apart from the steady improvement in the efficiency of gas lighting during the past few years, there has been a marked improvement in design and convenience. It is now possible to control gas lights from a distance by means of a pneumatic switch and special control cocks. Examples of these appliances should be fitted in every showroom; for this type of contrivance catches the eye of customers, and causes them to talk of the showroom to their friends afterwards. Then consider the effect of flooding-on half-a-dozen outside lamps when the daylight is failing, just by turning one cock. This convenience is still unknown to many people. Examples of concealed lighting also cause interest, and demonstrate the modern idea of "light on the object and not in the eye."

To encourage the public to talk is the root of all publicity work. Given a nicely-arranged showroom in a good part of the town, it would be futile to sit down and wait for orders to come along. The man in charge is a very important factor in the success of the scheme. He has to obtain the confidence of the public, and show them that the department are out to render service. He has to instil into the public that the whole knowledge, experience, and resources of his undertaking are available for their convenience, and that any service required, whether large or small, usual or unusual, will be rendered with absolute thoroughness. Above all he must be honest in his statements, even when it means the loss of an order, and he must fulfil all promises. The public are quick to notice when they are being treated in a straightforward manner, and they will come again, and perhaps send others. It is desirable to encourage people in these repeat visits to the showroom, and to encourage them to call in when they have a few moments to spare, whether they want anything or not. People entering a showroom should be allowed to walk round unmolested. Of course, a salesman can easily see when he is needed, and must be near at hand, ready to attend at the right moment. In some of the largest retail emporia in the world, prospective customers may walk from end to end of the premises without being asked what they require. In some quarters it is believed that this fact alone is responsible to a great extent for the progress of the concerns.

This "shop" effect needs to be encouraged, as the public are quite familiar with ordinary shops, and will walk round, perfectly at ease. But ask them to go into a "town-hall" type of building, and they at once loose their confidence, and become uneasy. Some showrooms are combined with the general offices; and, in the case of a lady requiring some small item—say, an odd mantle—she hesitates before facing the glances of an array of masculine officials, and gets the mantle from a small shop round the corner. The sale of this odd mantle is worth looking after; and the transaction should be carried through with as much importance as a twenty-pound order. Then the customer goes away pleased with the showroom, pleased with herself at commanding such respectful attention, and pleased with the article, for it is, of course, the best of its kind. The most important point is that she will in all probability come back again. Then perhaps the salesman may venture a "sale by introduction."

It is a good plan for a showroom attendant to try to forget that he is an official. He is a salesman or commercial man. The man in charge of the showroom should endeavour to obtain the confidence of builders, architects, &c. The medical profession, too, is very important to the gas industry; and all doctors should be catered for with extreme care, especially as regards heating. The gas fire is being used more and more for the sick-room; and very often the doctor has the casting vote as between gas and coal. To get the doctor on the side of the gas industry, it is obvious that he must first be satisfied with his own appliances; and trouble must not be considered in achieving this end. All appliances should be fixed with care, and special attention should be given to the supply pipes, so that each stove fixed may become a silent publicity agent.

Press advertisement, of course, enters into a publicity campaign, but this type of advertisement is rather expensive, as one insertion in a local paper will not have the desired effect, and it needs a series to make any impression. A gas exhibition is often a successful publicity agent. A well-organized and skilfully-arranged exhibition of gas appliances attracts an enormous mass of the public; and the results are felt for months afterwards.

The following actual facts will show the astonishing results obtained from this class of publicity. A few years ago a Midland gas undertaking decided to attempt a hire-purchase scheme for cookers. The necessary forms and books were prepared, and the showroom staff were posted with all information. In the course of twelve months or so, about two dozen cookers were put out on hire-purchase, and the scheme died unnoticed. A year or two afterwards the same undertaking decided to launch the scheme again. This time an exhibition of gas appliances was organized to inaugurate the scheme. Within nine months 2000 cookers were installed. Considerable business was done with simple hire and cash orders. Engines were fixed during this period taking an annual consumption of over 3,000,000 c.ft.

Plenty of leaflets should be distributed by the showroom staff. Every parcel of fittings, mantles, &c., should contain some form of advertising literature. Another suggestion as an aid to publicity is to set a window with some moving object.

To obtain the right atmosphere for the success of the publicity department, complete harmony must exist between all members of the showroom and fitting staffs.

Discussion.

The CHAIRMAN, opening the discussion, read a letter from Mr. F. Caudwell (Shrewsbury), in which he suggested that the word "education" should be stressed, rather than "publicity." It was of great importance to educate the consumer; and publicity did not invariably do this.

Mr. R. J. ROGERS (Birmingham) said that all true advertising was an educative force. He believed that it would pay an undertaking to hire a hoarding, and keep it filled all the year round with ever-changing poster appeals. Every form of publicity had its place and value, whether it was advertisement in local magazines, on gas accounts, or in newspapers. Education of the public had to be undertaken in a more subtle way. Some gas undertakings still thought it unnecessary to advertise. As long as this view existed the salesman's circles must keep hammering away to eradicate it. He emphasized the need for keeping all promises, and agreed that customers should be at liberty to stroll round the showroom. It was essential, however, that salesmen should realize immediately when they were needed. It might be well for the Circle to consider various methods of window dressing and display. He suggested that schemes for successful window displays might be sent in by members for criticism and consideration at some future meeting. In this way a valuable interchange of ideas might be effected.

Mr. G. BURDEN (Redditch) said that he had gathered many useful hints from Mr. Elson's paper which was published in the "SALESMAN" for April 29, p. 85. The literature supplied by manufacturers of apparatus, over-printed with local terms, was an effective form of advertisement

Mr. H. J. ANDREWS (Langley Mill) suggested that, in spite of all that had been said and written, some undertakings did not take sufficient trouble to assure themselves that the goods in their showrooms were really sound. With regard to local exhibitions, he advocated a "private view" by invitation, and the provision of afternoon tea. This he had tried, and found it a capital business-getting proposition. It also served to give the exhibition an excellent start. He had also adopted the policy of supplying apparatus on approval, and had found that less than 5 p.ct. was returned. This could be advantageously applied to the sale of gas irons.

Mr. C. W. WELFORD (Cheltenham) remarked that intermittent advertising was useless.

Mr. A. F. NEWBROOK (Stafford) said that his undertaking advertised gas apparatus on delivery lorries, telephone guides, local magazines, programmes, &c.; but local Press adver-

tisements had proved most successful. They regarded correspondence seals as an excellent form of publicity.

Mr. W. WILSON (Leamington) mentioned that his undertaking placed boards on all unoccupied property where they were making alterations or fixing apparatus. People always glanced at houses where workmen were engaged, and they therefore got a little free publicity. He asked if anyone had any literature relating to tumbler switch lighting, and would be pleased to hear of any advertising schemes carried out in the lighting field.

Mr. A. B. JONES (Derby) suggested that the personal touch was of greater importance in order-getting than any other form of publicity.

The HON. SECRETARY (Mr. W. L. S. Spinks) suggested that the title of Mr. Purcell's paper should have been "Service and Progress." He thought they would all agree that even pressures, good-quality gas at a reasonable price, the employment of skilled fitters, schemes of maintenance, and hire-purchase were among the essentials to progress. They could not, however, be termed publicity; they constituted service. The term publicity should be restricted to mean advertisement without reasoning. A certain amount of this type of publicity was necessary; but it covered less than half the field covered by the written and pictorial appeal. The poster, he thought, was one of the best and cheapest forms of publicity. They should fill advertisement space with "reason-why" advertisements.

Mr. PURCELL replied to the points raised during the discussion.

A vote of thanks, proposed by Mr. C. W. WELFORD, and seconded by Mr. P. F. COOMBES, terminated the meeting.

Scottish Circle.

THE GAS SALESMAN'S ATTITUDE TO ADVERTISING.

By W. M. MASON, Manager of the "B.C.G.A."

USEFUL EDUCATION.

I have chosen a subject which, though under continual study by those specially connected with publicity, demands the earnest consideration of business men generally. Those of us who particularly deal with the selling side of our industry should be clear in our own minds about the underlying principles and possibilities of good advertising as a means for boosting our own wares. Some of you may think you have enough to do without bothering with the things that the "B.C.G.A." is supposed to look after; but may I suggest that not only will the study of the principles and practice of advertising generally prove fascinating, but that the education and knowledge thereby gained will almost certainly prove beneficial to the salesman who devotes time to it.

One of the most encouraging things which I personally come across in my journeys throughout the country is the steadily increasing number of men (not necessarily the chiefs, on whom heavy duties and responsibilities associated with control and policy generally fall) who are as keen as if they were advertising agents on testing and trying-out their ideas and schemes in local publicity. The "B.C.G.A." is a national "pool" to which many of these men regularly contribute for the good of the whole, and from which they are glad to draw when occasion demands.

A WONDERFUL PROGRAMME.

We in the gas industry have such a fine story to tell—the story of national weal in coal conservation and the production of raw materials essential to industry, of communal well-being in supplying the most practical solution to the smoke problem, as well as increasing individual comfort and lightening labour in the home and workshop—that we may well be excused for waxing enthusiastic about it. The more we think and talk about our programme, the keener we shall become in spreading the story not in any spirit of "doing" the public for our own betterment, but only, and in every sense, in the public interest. It is just here that the great lever of advertising comes in. Even a Cabinet Minister is limited in his personal appeal; but, through the medium of the Press, and by the distribution of attractive literature, we can touch every home in our district, and nationally—if only we had the necessary wherewithal—every household in the land. One of the greatest possible sources of satisfaction to a right-thinking man is the happy fact that our business synchronizes with the public good.

I do not propose to give you a lecture on advertising in general—that is a proposition which even a World Conference such as was held at Wembley last year could not hope adequately to cover. I shall only endeavour, as I have said, to induce you to study seriously this great and fascinating subject for yourselves. Some of the points made at the Convention just referred to are worth repeating as concise statements indicating the place publicity holds in modern affairs. For instance:

ADVERTISING AS "CINDERELLA."

"Advertising is an essential art that conceals nothing. Its purpose is its power; and its purpose is to bring together the producer and the consumer for their mutual advantage in every market-place of which the toll gates are open or even half-open. It dresses the shop window for the inspection of mankind, and it attunes and harmonizes the seller's wares to the buyer's wishes."

"Economists have taught us in the past that there are three processes in business—production, distribution, and exchange—but an up-to-date economist to-day would certainly have to add advertisement."

It is a matter of more than passing interest that advertising, which has so often been looked upon as the "Cinderella" of business, is now regarded as a potent agent by means of which the trade of the world may be re-established. Art, Literature, and Science have all come into the service of this "Cinderella," who is coming to be regarded as the fairy princess, courted by the princes of commerce. Even a casual study of the advertisments in such a paper as "Punch" will speedily let you know "who's who" in big public business. The poster hoardings have been well named the art galleries of the poor.

Recently I read an interesting paper by Mr. Stuart Hirst, of Leeds, which contained many good things. Some of these I am going to pass on to you.

"A full realization of our dreams of trade supremacy hinges less upon improvements in, and labour saved on, production than it does upon a revolution, in many cases, of our ideas and methods of merchanting and salesmanship. In this country we are often better manufacturers than we are merchants."

GAS PUBLICITY FIGURES.

That is a statement applicable to the gas industry. The engineering or production end of the business has been, and is being, done admirably. The business development side is largely at the beginning. I do not for a moment suggest that there are not good business men in the industry. This would be foolish and untrue; but there are not many men as keenly alive to the investment value of modern service and publicity as there are to the essentials of (say) good engineering practice. Take the financial side of it. On the works a new installation of plant involving heavy capital outlay is, as a rule, undertaken i the engineer can demonstrate the need fo it; but how difficult, in many instances is it to get adequate expenditure for publicity and sales development. The Wembley Gas Exhibit Fund last year, and this is, we hope, an indication that many o our administrators are coming to appreciate the value of wise publicity; but ever in this connection many failed to respond to what is undoubtedly a splendid opportunity for useful propaganda.

After twelve years' specialized effort we are proud of the fact that over 90 p.ct. of the industry collectively contributes to the "B.C.G.A." something like £40,000 annually to be spent on advertising the service which gas can render the community and the nation. A generous estimate would perhaps double this sum as being spent directly in local publicity by gas undertakings and by manufacturers of appliances. In comparison with this figure, some individual business houses in London spend more. Figures recently quoted at a Salesmen's Circle gave the estimated revenue of the gas industry as approximately forty million pounds, and the total spent on publicity as £100,000, or only about 0·002 p.ct. of the income from gas alone. In this connection the following statement made at the Advertising Convention is significant:

ADVERTISING UTILITIES.

"The work of advertising the utilities of their service has hardly more than commenced. American public service corporations are now spending from one-quarter to one-third of one per cent. of their gross income for advertising and publicity. In other words, their annual expenditure for selling securities, building goodwill, &c., now amounts to something more than $12,000,000. In well-ordered private business the minimum expenditure for advertising amounts to about 2 p.ct., and the maximum runs as high as 8 p.ct. If the utilities were to spend as much as the minimum set aside by private business for advertising, their expenditure for this purpose would be $80,000,000."

In face of these figures of American expenditure, and in view of the fact that competition is rapidly increasing in strength and political backing, surely the time is ripe for greatly altered views on the whole subject. If the gas industry could be sold as a going concern to a big business man like the late Lord Leverhulme, for instance, and the wonderful "selling" possibilities from a national and communal point of view fully realized, would there not very speedily be inaugurated a popular "boom" for gas such as we have never even imagined?

It may be said that this is much more a matter for consideration by seniors and administrators than by salesmen. This is true, and action can only come from the top; but—and this is the main thing I wish to emphasize—salesmen can form their own intelligent opinions, and train themselves by study to take a thoughtful interest in this whole subject, and so be in a position to influence, whenever possible, a sane and right consideration of advertising as a great modern method of consolidating and developing business.

"Quality, price, and service are the cardinal virtues of successful trading, but the greatest of these is service;" and service must include the regularly-sustained education of the consumer. In ordinary business, a sale completes the transaction; with us a sale begins the job.

"The idea of service has to be conceived on big, generous lines, and applied sympathetically in every walk of commerce. Service not merely teaches us to help our customers in their reasonable, and sometimes unreasonable, demands. It teaches us to take, if we wish to prosper, their point of view in preference to our own, to produce the goods that please them first and ourselves last; and it teaches us that it is our

duty—our individual as well as our patriotic duty—to produce goods of the best sort, and always at the lowest marketable price. If we do less than this we are not worthy of an honourable place in the trade of a proud city and in the economic life of a great nation."

ADVERTISING AS A SELLING FORCE.

Concurrent with a changing of the old order of things, the producer is called upon not only to study more closely the wants of his customer, but to discover better and cheaper methods of satisfying these wants. More than any other important force in commercial life, advertising is often misunderstood, and as often again misapplied. It is by no means the specific for all our commercial ailments that some of its zealous advocates would have you believe. In the gas industry advertising will not make up for lack of service in other directions; it will only make the faults more glaring. Nor will the "B.C.G.A." national advertising do all that is required. Local and district advertising is essential to supplement the national. Several of the larger undertakings are now spending more in local publicity than their contributions to the "B.C.G.A." In one instance the amount is more than double, and runs into many thousands of pounds annually. One of the largest and most efficiently handled companies in the North of England actually spends six times more on local than on national advertising—*and it pays to do it.*

Advertising, rightly used at the right time and in the right place, is the most economical selling force in the world today. That is true whether you are concerned in the merchanting of goods or in the exploitation of a nation's cause. Advertising moulds national sentiment by the same motive power that it stimulates the public demand for Scotch tweeds or "Sunlight" soap. Propaganda and publicity are just different names for this same vital force.

ADVERTISING FROM THE RIGHT ANGLE.

The first thing that it is necessary to do is to view advertising from the correct angle. So many people who cannot see the wood for the trees have a very confused idea of its scope and appropriate uses. Think of advertising not as a mere adventitious aid, but purely and solely as a selling force in the business in which you happen to be engaged. Advertising does not raise the cost of goods to the public. In very many cases it actually succeeds in reducing the price, owing to improved and bigger production that follows the demand caused by the advertising. It is a frequent experience that advertised goods, besides being better, cost less than avowedly similar goods which are not advertised.

In gas administration it is surely a basic principle that, by spreading standing and capital charges over a bigger consumption, the price can be reduced to the consumer. Profits are made—or lost—in the board-room. It is a wise policy that brings continued success.

The four principal channels of publicity all bear the same initial. They are: The Press, the Poster, the Pamphlet or Catalogue, and the Personal appeal of the salesman or the mailed letter.

I shall not attempt to deal at length with these sections in detail; each is an interesting subject in itself.

VALUE OF THE PRESS.

The Press, under which classification, of course, I include the newspaper proper and almost countless magazines, owes its value as an advertising medium to the fact that it goes into the home (where the commercial traveller cannot hope to penetrate with his arguments). Our newspapers are read in moments of ease and leisure, and generally under conditions peculiarly favourable to the germination of new wants in the mind of the housewife or breadwinner. You cannot make a wisely-designed and properly-displayed appeal to 100,000 homes (or 10 million for that matter) through the medium of our daily newspapers without a reasonable expectation of creating some useful impression. The reality of the powerful advertising force that is being exerted almost unnoticed in our midst had recently a peculiar illustration, when all the newspapers in New York stopped publication, owing to a strike. Due to the absence of advertising, shopping business came automatically to a standstill. It is stated that, had the strike continued in full force for any length of time, there is little doubt that a disastrous blow would have been struck at the city's trade, and that many establishments would have been obliged to close-down.

From this illustration it is easy to conjecture what disturbance to our domestic and economic life would occur if suddenly, from any cause, the flow of advertising force—so silent, yet so mighty—was diverted or made to cease in this country. In all this it is to be remembered that what applies to business advertising generally, also, on principle, applies to gas.

Why should the utility business be any different from any other business when it comes to advertising? "Because it is a monopoly, and people have to come to it for service whether they wish it or not," say some supposedly intelligent people.

Advertising is accepted to-day as a necessary part of business, and advertising costs as a necessary part of the expense of doing business. In the utility business it not only helps to increase the consumption of the utility's product, thereby causing reduced rates through a wider distribution of the fixed costs of doing business, but it also is used to win the goodwill of the consumer. This last is surely an important method of keeping-down costs of service.

ADVERTISING PUBLIC UTILITIES.

The following resolutions passed at the Advertising Convention sum-up concisely the need for public utilities—including municipal and company gas undertakings—to advertise.

"That this Conference is of opinion:—

"(1) That it is as important to advertise the services which public utilities can render to the community as it is to advertise the goods of firms which have no monopoly rights of supply.

"(2) That goodwill, based upon equitable policy and 'service-first' principles, is essential to the permanent prosperity and persistent progress of public utility undertakings.

"(3) That advertising is esential to the establishment and maintenance of such goodwill.

"(4) That fully educated, efficient salesmen are equally essential.

"(5) That the possession of a monopoly, whether by a company or a municipality, imposes on its administrators the duty of a policy of progressive business methods, in the interests of consumers, as well as of stockholders or ratepayers."

The Editor of one of our technical papers was right when he recently wrote:

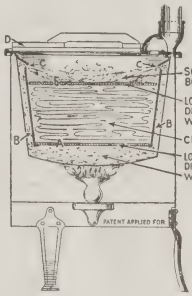
"Some people rely upon making the competence that is to care for them in their old age through the vagaries of chance; hence the lure of the oil stock promoter, the gold brick boys, and the backers of Monte Carlo. Most of the people, however, believe in the principle of working for the future through some well-planned system of saving and investing. To them the vagaries of Lady Luck possess no charm.

"Public Utilities can follow either of these paths. They can 'take a chance' and let the public form its own conclusions, or they can build for the future by some far-sighted plan. The gas industry is coming to a point where it is in direct competition with oil, coal, and electricity for the heating business of the country. A well-developed educational plan through consistent advertising will make the people realize the advantages of gas over other fuels, and will keep these advantages fresh in their minds at all times."

I have tried to avoid overloading this brief address with "indigestible" matter. My main object has been to stimulate interest in a subject the study of which is fascinating even as a hobby, but which, to the "live salesman," will prove a most profitable process in general culture and education.

A Gas-Heated Wash-Boiler.

Next in importance to the gas cooker and the fire, comes the gas-heated wash-boiler. This has long been appreciated in areas of dense population, where these appliances are used in vast numbers. The gas wash-boiler saves time, labour, and space, and is clean, thoroughly efficient, and economical.



Arden Hill's "Whirlpool" is an example of a boiler which will turn the most arduous wash-day into a day of comparative ease for the housewife. Fill the boiler with water, add soap; and the moment boiling point is reached, the imprisoned steam at the bottom of the pan forces the water up the tubes in the manner shown in the illustration. Emerging from the slotted heads of the tubes in a rapid and ample flow, the boiling water makes its way through a perforated top-plate, then through the clothes and the lower-plate, to be forced once more into circulation through the tubes. The hot soapy water is circulated through the clothes a number of times; the flow being equivalent to 200 gallons per hour.

The outer case of the "Whirlpool" boiler is made of strong durable galvanized iron. The inner pan is of tinned copper; and a combined flue carries-off the gas and steam products. A plate, pierced with a number of holes, slides down the inside of the pan, and rests at the ends of three circulating tubes, leaving a shallow chamber between it and the bottom of the pan. Little or no attention is required after the boiler has been filled with water, the clothes put in, and the gas turned on, for the circulating process takes place automatically when boiling-point is reached.

Literature illustrating and describing the "Whirlpool" and other gas-heated wash-boilers will be sent on application to Messrs. Arden Hill & Co., Acme Works, Salford Street, Aston, Birmingham.

Up-to-Date Cookery.

The other day we heard of a consumer being persuaded to replace his gas cooker by an electrical one. The electrical engineer who took the order accepted the gas cooker in part payment, and *had it installed in his own house.* The moral is that of ancient days: "Actions speak louder than words."—South Metropolitan Gas Company's "Co-Partnership Journal."

South Wales and Monmouthshire Circle.

A Meeting of the Circle was held on May 15 at the Gas Offices, Bute Terrace, Cardiff—Mr. DAVID MUIR, Engineer and Manager, Pontypridd, presiding.

The CHAIRMAN delivered the following

ADDRESS.

The question often occurs to me, Are the services of the salesman being utilized to the fullest degree for the sale of gas-works commodities, and do gas undertakings generally give sufficient assistance to equip the salesmen for the strenuous battle in which we are engaged to attain a purer and healthier atmosphere?

At the outset I would exonerate the larger undertakings who have well-trained salesmen in every branch; but a great many of the smaller undertakings, and even medium-sized ones, do not put sufficient impetus into the selling business. A gas salesman should not have his energies confined solely to the sale of gas appliances. He should be able to push the sales of coke, tar, sulphate of ammonia, and any other bye-products manufactured on a gas-works. The sale of ordinary gas appliances is on the whole pushed with considerable vigour. How many salesmen, however, try to sell some of the other useful commodities of a gas undertaking?

For example, the salesman, we will assume, has failed to sell a gas fire. Does he try to obtain business for his undertaking by informing the prospective customer that good heating service can be obtained from coke manufactured at the gas-works? If he has satisfied the customer with the appliance required, does he diplomatically turn his talk to the subject of gardening, which is of more than passing interest to most people? If he did, he would get an opportunity of discussing the benefits to be derived from the use of sulphate of ammonia. Tar could be talked about—for making pathways, and the preservation of fencing. Perhaps the customer is the owner of a motor car. Does the salesman grasp the opportunity of bringing to the customer's notice the use of benzole, which is manufactured in some gas-works? Perhaps the customer is keen on poultry rearing. Does the salesman impress on the customer the use of gas for his incubators and brooders, or creosote for the preservation of his poultry buildings, and for killing red mite?

Do undertakings always purchase the best fittings and appliances for the salesman to sell? I fear they do not. Undertakings generally do not make it a rule to test fully the appliances purchased, so as to obtain reliable data regarding consumption and efficiency. The result is that the salesman in a great many instances has to rely upon the information gleaned from catalogues. What is the result? A salesman sells an appliance based on these figures, and in practical working the results are not obtained. The customer is naturally displeased; and the seeds of displeasure are sown among his intimates, to the detriment of the gas undertaking.

Again, assuming that the salesman has sold a first-rate appliance, and has given correct information regarding its capabilities, does the undertaking always back-up the salesman by having a meter and service pipe put in of sufficient capacity to do the work required? Does the undertaking always take steps to ensure sufficient pressure throughout the district?

Does the average gas salesman have the opportunity of becoming conversant with the various bye-products for sale? No. This could be overcome by the technical staff co-operating with the sales staff, and educating them in this branch of gas-works practice. Greater facilities could be offered the salesman to obtain a more intimate knowledge of the work performed in the gas-works, thereby strengthening his hand.

Chiefs of gas undertakings should avail themselves of every opportunity to address meetings of Chambers of Trade, Rotary Clubs, and Trade and Labour Councils, &c., in order to prepare the ground for the salesmen.

If more attention was given to the failings enumerated in these random notes, greater service would be rendered by the gas industry to the community at large.

Immediately afterwards the Chairman called upon Mr. A. W. Stickler, Cardiff, to introduce for discussion:

RAMIFICATIONS OF DISTRICT WORK.

By A. W. STICKLER, of Cardiff.

The outdoor staff calls for highly skilled men who have had training in practically every branch of the gas industry, in order to enable them to deal thoroughly and competently with everything that may occur in the course of their duties. It is of the utmost importance that they be cheerful, courteous, good-natured, and prepared at all times to give good service to the consumer and their undertaking.

The opportunities afforded the meter inspectors for pointing out the advantages of gas and coke as smokeless fuels are numerous; and advantage should be taken of them. How easy it is for the meter inspector to distribute literature about various appliances. Inquiries could be followed up by the sales staff. Collectors, inspectors, estimators, and foreman fitters, should be in a position to give prices and terms of all gas apparatus their undertaking offers. This would obviate the necessity for a second call.

In Cardiff we are making a census of all gas appliances in use on the consumers' premises, and by doing so we are increasing the sale of gas. Briefly, the following is our procedure. A letter is sent to the consumer advising him that a representative will call to inspect the gas appliances in use, and offer advice regarding the economical use of gas. A call is subsequently made, and the registration of the meter is taken. At the same time the representative examines the service pipe, checks the size and number of the meter with a record card, and tests it for escapes and registration. He then inspects the appliances, carries out minor adjustments, if necessary, and points out where additional apparatus could be installed to the advantage of the consumer. On returning to the office, he hands-in a record card giving full particulars of the appliances in use, stating their condition and the prospect of new business, together with orders taken during the inspection. This record card is filed, and reference is made to it from time to time. Where there is any possibility of new business, periodic visits are made.

The "inspection canvass" has the following advantages:

1. The examination of the service pipe is a precaution against accidents.
2. Meter testing assists in reducing the unaccounted-for gas, and indicates whether the apparatus receives an adequate supply of gas.
3. Registration records constitute an intermediate reading.
4. Examination of consumers' appliances, minor adjustments, executed by the representative, and advice given, maintain the confidence of the consumer.
5. A record of appliances in use on the district indicates the possibilities of new business.

NEW BUILDINGS.

To further the sale of gas, progressive undertakings offer to builders services free up to a certain length, providing they lay a number of points of a specified size. Most builders take advantage of this concession; but the laying of points does not guarantee a consumption of gas. It is our duty to see that appliances are installed.

A consumer always wants his meter and cooker fixed before he occupies a new house. In nine cases out of ten, he will go into the showroom to give his order. Co-operation between the showroom and those engaged on the district is necessary. If the showrooms were supplied with a record of buildings in course of erection, with the particulars of the points laid in each house, and the most suitable appliances to instal, it would assist the showroom manager to increase his sales.

DISPUTED ACCOUNTS.

If a consumer is convinced that he has not consumed the amount of gas he is charged with, the following procedure may be adopted:

1. Ask the consumer if it is convenient for you to test the meter for escape.
2. Inspect the consumer's appliances, and point out where there is a possible waste of gas.
3. Take into consideration the number of days compared with the corresponding quarter.
4. Inquire if there has been illness in the house, and if additional apparatus has been installed, or any fittings have been repaired during the quarter in dispute.

CAPPED SERVICES.

A considerable amount of unaccounted-for gas can be traced to defective services. Therefore it is necessary to make a periodic inspection, especially of those that are capped, and not cut-off from the main. It is first necessary to keep a record of all such services, and their condition when inspected. Capped services are usually in unoccupied premises; and this makes an inspection more important, as it is possible for a slight escape to result in accumulation of gas in a cellar or building, which might lead to a serious disaster. From a recent inspection, it was found necessary to cut-off several old services from disused premises.

To give an adequate supply of gas to flats and suites of offices, there are many items to be taken into consideration—size of service, meter, internal pipes, &c.

Avoid fixing secondary meters. This practice is far too prevalent. Fix separate services in all premises where there is more than one consumer to be supplied.

Discussion.

Mr. C. KNIGHT (Cardiff) said that the practice of notifying showroom assistants of supply pipes, &c., being laid in new buildings was of great advantage.

Mr. C. COLLINS (Newport) mentioned the carcassing of new buildings. Instead of arranging with builders, it was better to see the prospective tenants, with a view to installing gas appliances.

The HON. SECRETARY (Mr. B. J. Bell, of Cardiff) said that in Cardiff they were offering certain concessions to builders, which were proving most satisfactory. A canvass of the district had proved a huge success. One good feature was the opportunity afforded of getting into personal touch with consumers.

Mr. H. S. BARTLETT (Cardiff) proposed, and Mr. BAILEY (Cardiff) seconded, a vote of thanks to Mr. Stickler for his paper.

The proceedings terminated by a vote of thanks, proposed by Mr. G. STEEL, to the Cardiff Gas Light and Coke Company for the accommodation placed at the Circle's disposal, and for the hospitality extended.

Truth in Salesmanship.

By Thos. Newton.

Truth in salesmanship is one of the many desirable qualities which all gas salesmen should possess. Every customer gives an honest deal; and in business, as in other walks of life, honesty is the best policy. The world's professional advertisers have so much regard for truth in their business that they have enshrined it in a slogan, "Truth in Advertising." This is reflected in the restrained advertisements of to-day as compared with the irresponsible advertisements and impossible claims of a bygone age. Advertising has not suffered as a consequence. Indeed, it has made, and is making, rapid progress. Adherence to the truth has directly promoted development, in which the choice of words, telling phrases, and apt quotations are blended together with obvious sincerity and candour.

Truth in advertising necessarily implies truth in salesmanship; and in the absence of advertising, truth in salesmanship should nevertheless prevail.

In connection with the sale of gas appliances, a sound knowledge of first principles is essential; and the gas salesman, having this knowledge at his disposal, not only need not fear the truth, but, on the contrary, should welcome it. He is in a particularly strong position when dealing with prospective customers—especially when he is thoroughly acquainted with the wares of his rivals. To tell the truth in these circumstances should be a delightful task; and the gas salesman will find that the pleasure is proportional to his knowledge of the subject. There can surely be no more deplorable state of affairs than a conscious or an unconscious deviation from the truth simply through lack of knowledge. Any false or misleading statement made will most assuredly "come home to roost."

It will therefore be seen that knowledge is a direct aid to truth in salesmanship, and particularly as far as the gas salesman is concerned. The moral, of course, is obvious. The gas salesman should not only have a general knowledge of his business—that surely should be regarded as the minimum—but he should also possess the knowledge of the specialist. For example, he should make himself thoroughly conversant with the special features and characteristics of the various gas appliances now on the market. A sound knowledge of these will enable him to give competent advice in a confident manner as to which appliance can be relied on to render the best service in given circumstances. It is also essential that the gas salesman should memorize the gas consumption, per hour, of each type of appliance he is called upon to handle; and a knowledge of efficiencies relating to gas appliances would make him more a master of his business than he would otherwise be.

Truth in salesmanship is specially desirable when stating the hourly rate of consumption of a given gas appliance to a prospective consumer. There should be no trifling with the truth in order to force a sale, since, apart altogether from ethical considerations, this is quite the wrong policy to adopt. A cleverly-engineered sale based on misrepresentation is little short of a calamity, the dire consequences of which will certainly be revealed a few weeks after the sale.

Whatever qualifications a salesman may possess, he may be classed as a failure if he omits to give satisfaction to his customers; and one of the surest ways of causing dissatisfaction is to understate or misrepresent rates of consumption. When once a customer's confidence is destroyed, the gas salesman, instead of being regarded as a trusted adviser, is treated with suspicion; and business suffers as a direct consequence.

Keenness and competence are commendable qualities in any gas salesman, but he who would excel in both qualities must possess a sound knowledge of his business. The possessor of the knowledge here referred to can fearlessly adopt as his motto "Truth in Salesmanship;" for no industry stands to gain more from the dissemination of the truth than does the gas industry. In this connection, competence may be said to beget truth; and for this, as well as for other reasons, it is greatly to be desired.

Truth in salesmanship is not merely confined to the spoken word, since impressions can readily be conveyed by looks and gestures. It is a mistake to do lip-service to truth, and at the same time to convey the opposite impression by every look and gesture.

How often, in other businesses, do we find inferior substitutes offered with plausible language and insinuating gestures which are apt to mislead the public into thinking that the substituted article is much superior to the one originally required? Yet the bare truth may be that the trader is temporarily out of stock of the original article; and rather than miss a sale he unblushingly resorts to subterfuge.

It frequently happens, of course, that what a customer asks for is not the article which is best suited for his or her particular requirements. In these circumstances, it is right and proper to point this out in a courteous and tactful manner, and then offer something calculated to give greater satisfaction. It would obviously be a great mistake to sell an article or appliance which is not suitable for a customer's particular requirements simply

"GAS SALESMAN'S" Diary and Handbook

11, Bolt Court, Fleet Street, London, E.C. 4.

because he happened to be ignorant of that which would best serve the purpose.

Every customer is entitled to fair and candid treatment. If, therefore, a customer happens to err, through lack of knowledge, while stating his or her requirements, the least a gas salesman can do is to point out the error, fairly and candidly, yet as diplomatically as possible, in order to prevent the perpetuation of erroneous impressions. Nothing is so disastrous as the suppression of truth; and nothing is so difficult to rectify as false impressions when once these have become more or less established.

As regards the capabilities of various gas appliances now on the market, it is much better, and more satisfactory in the long run, to under-state than overstate possibilities. Care, however, should always be taken to render full justice on all occasions. Truth in salesmanship implies that, while, on the one hand, there should be no exaggeration or inflation of claim, on the other hand it is equally important that due emphasis should be laid on all the good points and qualities of the article or appliance under consideration. The good gas salesman, of course, would never dream of allowing anyone to depreciate the merits of an appliance which he was confidently recommending, and which he was thoroughly satisfied would fulfil the customer's requirements. In all his dealings, however, the salesman should take particular care that the promise does not exceed the performance.

Most gas undertakings, nowadays, have to compete with outsiders in the sale of fittings, burners, mantles, and all kinds of gas appliances; and it is really surprising what a lot of shoddy goods are being offered to the public by competing firms whose one and only object is to sell them, irrespective of whether or not they are likely to give satisfactory results. It is, of course, a commonplace that many complaints as to the quality of gas should more legitimately be levelled against these trashy and inferior fittings.

Here the gas salesman has a splendid opportunity to assert the truth, and at the same time to educate his prospective customer. Inferior fittings, burners, mantles, &c., may perhaps cost less initially; but invariably the running costs are higher, and the efficiencies lower, than they should be. What should be borne in mind is that the running costs and the efficiencies are remembered—being ever present—when the initial cost has long been forgotten.

A vigorous campaign based on truth in salesmanship would soon spell the doom of much of the trash; and in this campaign no person can play such an important part as can the gas salesman.

Hospital Economy Helps Smoke Abatement.—London could abolish its smoke pall, increase its sunshine, turn fog into mist and darkness into light, if it would follow the significant lead of its medical men and its hospitals, and use cleanly smokeless fuels. It is an interesting fact that the highest consumption of smokeless gaseous fuel per acre in any residential district is in the Harley Street area, which, as everyone knows, is occupied by our leading physicians and surgeons, and that to-day the great majority of the London hospitals (and especially those dealing with tuberculosis) are large consumers of gas for heating and other purposes. Some of them have two hundred or more gas-heating stoves within their walls. Westminster Hospital, which was recently enlarged and remodelled, has almost this number in use, as is shown in the current issue of the "B.C.G.A." "A Thousand-and-One Uses for Gas," which is illustrated by numerous views of its wards, kitchens, nurses' quarters, and so forth. Recognizing the continuous drudgery, dirt, and noise involved by the use of coal, the hospital authorities have almost completely eliminated it from the building, and in doing so have saved much valuable space that would otherwise have been required for storage purposes. Thus do economy and hygiene march hand in hand.

The Gas Boiler and Circulator.

A series of twelve papers prepared by Mr. FREDERICK W. DYE, and published by permission of Messrs. John Wright & Co. (Radiation Ltd., Proprietors).

PAPER XI.

THE EFFECTS OF HARD AND SOFT WATERS.

Broadly speaking, hard water is that which carries lime in solution, while soft water is deficient in lime. The quantity of lime is spoken of in "degrees of hardness"; each degree being a grain of lime per gallon of water. Hardness is of two kinds—permanent and temporary. The former does not cause a deposit of lime when the water is heated; the latter makes the familiar deposit of lime commonly spoken of as "fur," in kettles, boilers, and similar water heaters. The hot-water fitter need not concern himself with the permanent hardness, but only with the temporary. The local water company will state what the temporary hardness is.

Water is considered as soft when this does not exceed 8°. Liverpool may be taken as having a very soft water (from Lake Vyrnwy), the published hardness being 1·5°. London averages 16°, and is always called a "hard" water, though not excessively so. Water of 20° would be spoken of as very hard, while below 16° such terms as "moderately hard" downwards to "moderately soft" and "soft" would be used.

HARD WATER.

An advantage peculiar to hard water is that the rusting of iron and dissolving of zinc and lead do not readily occur. In London, great numbers of hot-water installations consist of plain iron boilers, plain iron pipes, and galvanized-iron storage tanks; and no discolouration of the water by rust occurs if the apparatus is put to use soon after its erection. If water is allowed to remain stagnant in the new pipes and parts for any length of time, rusting and discolouration are experienced, but even these disappear after a period of regular heating and use. The wise engineer, however, uses galvanized pipe, as he cannot always tell whether first conditions may not favour a little rusting, with complaint following. Galvanizing the pipe is sufficient protection until the hard water can have its own protective effect, which means the deposit of the first film of lime.

The accepted explanation is that the rusting of iron does not occur freely in the presence of lime. The success of reinforced concrete construction is some proof of this, as the iron reinforcement does not perish. The writer has also carried out many experiments showing conclusively that lime has this good effect, whether in the form of chalk, lime, or cement.

The disadvantage of hard water is that the lime deposited from it, when the water is heated, accumulates and hardens, forming an incrusted mass in the boiler—usually on the surface where the greatest heat is felt. This not only prevents the water having contact with the iron, but, being a poor conductor of heat, the metal presently becomes injured, much the same as if there were no water in the boiler to keep the metal at a low non-destructive temperature. In other words, the metal is caused to fracture or perish, which shows itself in the form of leakage. Apart from injury to the boiler, a loss of fuel (gas) occurs, owing to the lime resisting the passage of heat, by reason of its low heat-conducting quality. Recognized authorities have stated that an incrusted deposit of lime of no greater thickness than $\frac{1}{8}$ in. makes it necessary to burn 15 p.ct. more fuel for a given result.

The measure to be adopted with boilers in hard-water districts is to open and clean them at regular periods. The deposition of lime is in ratio to the hardness of the water, the number of times the water is changed in the boiler (that is, the quantity used), and the temperature to which the water is raised. It has been stated that lime is not deposited from hard water until it reaches a temperature of 150° Fahr., but in practice this is found to be incorrect. It is known from experience that the amount increases as the temperature rises; and, as gas boilers are fitted with thermostats to limit the temperature, the deposit of lime is limited also, which is highly desirable.

The chief cause of variation in the amount of lime in boilers (in a district which is served by only one water company) is the amount of fresh water heated and used—which is always an uncertain quantity. As a general rule, with water of London hardness, and its heat limited by a thermostat, and the boiler fitted in private residence of fair size, annual cleaning is sufficient. In small properties the time may be extended; while in business establishments, half-yearly, or even quarterly, cleaning may be found necessary. Reasonable judgment must be used; and the desirable plan, with all new boilers, is to book a date for first opening and cleaning, when the state of the boiler will be a guide for future regular attention.

NOTE.—The boilers supplied by Messrs. John Wright & Co. are treated internally with "Anti-scale," which prevents the lime adhering so firmly to the metal. It is not claimed that this treatment reduces the quantity of lime, but, by preventing its close adherence, cleaning is facilitated, while the metal is not so greatly affected by the heat. Regular cleaning is still as necessary, but is more easily and perfectly done.

SOFT WATER.

The chief advantage of soft water is in its being agreeable to use, and needing less soap for washing purposes. Its disadvantage (to the hot-water engineer) is that it attacks iron, zinc, and lead. Galvanizing the surface of iron pipes, &c., is no protection, for the zinc soon goes. There is a general belief that the action is worst when the water comes off moorland districts, which gives it a slightly acid quality. In all districts served with water of this kind, the use of iron must be avoided. In a number of such places iron boilers are used which have been treated by the Bower-Barff process, while in others it is the common rule to employ copper boilers, copper cylinders, copper or lead pipes, and slate cold-water cisterns. The action of this water on lead must be rather slight, as lead pipes are commonly installed, and last well; but the action is sufficient to make the water unsafe for drinking purposes.

When copper pipe is used, the practice is to have a quality which will allow of its being screwed iron thread, for which brass or gunmetal fittings can be obtained from plumbers' warehouses. If this quality entails too high a cost, a lighter pipe can be obtained, this being screwed with a finer thread. Certain makers of copper tube supply this pipe, loan the tools for screwing it, and supply suitable fittings.

A common experience is that copper pipes with screwed joints (using red and white lead and hemp, as with iron pipes) do not remain sound; and a number of engineers consider it necessary to "tin" the threads with solder before screwing up, and afterwards to apply the flame of a blow-lamp. There are several patented methods of jointing copper pipes without a screw thread, with which a light tube may be used (and will last well); but it is not within the province of this paper to describe them. They are advertised in trade journals.

When employing lead pipe, plumbers' wiped joints are the rule; and the impor-

nt point to remember, and guard ainst, is the liability of this pipe to ngthen and sag when used for hot ater. It has been suggested that lead pe expands to a certain extent when ated, but does not contract to the same tent when cooled. The fact, however, that, after expanding, if the pipe exriences any resistance in contracting, it liable to stretch, and so become gradually lengthened. The rule to be observed, erefore, is that lead pipes for hot water, hich are in a horizontal direction, shall ways rest on wood fillets if on a wall; on boards if in a roof; or shall be supported in this way, every inch, wherever ey may be run. When run in a vertical irection, the pipe should have lead tacks " soldered on to it, to allow of its sing secured to the wall in a permanent anner; for no kind of hook or holdast can ensure such even and sufficient pport.

FAULTS.

Only what be termed principal faults an be referred to. Unusual, or more bscure, failings are seldom encountered.

Faults which may be found in the hot ater apparatus already in the customer's ouse, and to which the circulator is to be onnected :

(1) *The Flow Pipe* from the range oiler to the upstairs tank may terminate oo low in the tank. This *must* be corected (see Paper IV.). It entails removing the lid of the tank, which is a roublesome task, but one which has to e done. With a storage cylinder downtairs, the pipes from the circulator should ot join the range pipes (see Paper VI.); onsequently the range pipes then need no consideration.

(2) *The Cold Water Supply Pipe* may e connected into the bottom plate of the ank or cylinder; and if it has no fitting ttached to it inside, the cold water will be delivered vertically and bore up to the top of the storage tank. (See Paper IV.) It is of importance that the cold water be delivered horizontally inside the bottom part of the tank, or cylinder, as described in Paper IV. This must be put right.

(3) The storage tank or cylinder may be larger than is needed, and too big for the boiler. It has been explained elsewhere that the storage should not exceed half-a-gallon to each cubic foot of gas burned at the boiler when burning full on. Thus, a burner having a maximum consumption of 80 c.ft. per hour will work well with a storage tank up to 40 gallons. If the storage is considered to be too great, as above stated, it can, if a downstairs cylinder, be given a less active capacity, as described in Paper VI. (fig. 19), or can be reduced generally, as Paper VII. (fig. 20).

(4) *Exposed Pipes.* — The circulating pipes in the house may be so long, and so exposed—the upstairs tank, too, possibly being in a cold place—that some fear may be felt that the heat losses will make the boiler appear to be of low efficiency, with the certainty of an excessive gas consumption for the duty performed. It is best to consider that everyone will complain at both these things; and preventive measures should be adopted at the beginning. The cost of heat losses in money figures, and the available means of preventing or reducing them, are fully set out in Paper X.; while in Paper V. is described the somewhat simple means of converting the upstairs tank to the downstairs cylinder system, with great advantage to the consumer, as well as to the boiler.

(5) *Secondary Circulations.*—In residences of fair to large size, with storage cylinder in the kitchen, there is often found a pipe circuit extending from the top of the cylinder to the various taps, and, as this has hottest water circulating through it at all times, and is hot from end to end, the heat loss (and gas consumption) may be as bad as described in the last " fault " (4). In a few instances the circuit may be found unnecessary, and the customer willing to have it stopped off. In others, some thought has to be given to covering the pipe, as described in Paper X., while a means of ending the night losses and retaining what hot water there is in the cylinder is described in Paper V., fig. 15.

Faults which may be discovered after the circulator is fixed :

(6) *Exceeding the Maximum Gas Consumption on the Makers' Card of Directions.*—This is unlikely to occur with a gas official, but he will find it a too common thing when following-up complaints. Excessive consumption defeats itself, usually by causing smothering, besides which the gas flames may be devoid of cones, and less effective. Ordinary pencil-shaped flames should have well-defined, sky-blue cones, and in all cases the burners should be adjusted not to exceed the makers' maximum. The common consumptions for two different sizes of boilers are 40 c.ft. and 80 c.ft. per hour respectively, which are equivalent to 2 c.ft. and 4 c.ft. in three minutes, which can be easily and quickly observed at the top dial of the gas meter, if no other gas is burning at the time. It is easy to fall into the error that a greater gas consumption will ensure an increase in the quantity or temperature of the water being heated, but it is an error when the makers' figures are exceeded.

(7) *Flue Troubles.*—It is too commonly thought, by those outside the gas industry, that any kind of flue, or even no flue, suffices for a gas boiler. The subject is fully treated in Paper VIII.

(8) *Time Taken in Heating Water.*—Many consumers take too sanguine a view

WALTER KING, LTD., "GAS JOURNAL" Offices, 11, Bolt Court, Fleet Street, LONDON, E.C. 4.

of what a gas boiler will do—they think it resembles a geyser, and is another kind of instantaneous water heater. Where the great difference exists is in the rate of gas consumption. A circulator burns (full-on) 40 to 80 c.ft. per hour; the geyser (say) 120 to 200 c.ft. It follows that the geyser is about three times as quick; but the customer does not realize the great difference in the amount of gas burned in a given time. A small circulator is often well suited for a small house, but there may be a warm bath wanted before breakfast. The gas consumption (full-on) is 40 c.ft. per hour; therefore, it takes one hour for a bath, which is thought to be an unreasonable, perhaps an impossible, time to wait. In addition to the time taken, so many think the gas consumption is too great (because of the time taken), it having often been said: "We have to burn the gas for an hour to get a bath, and we are sure that it costs a shilling." The cost is possibly 2d., and the customer looks incredulous when told that the best, or the worst, that the boiler can do is to burn twopennyworth of gas per hour. This subject is included under "faults," as it is one that should be introduced to the customer and made clear, preferably before the purchase, after which it should not be regarded as a "fault."

Useful Information for Gasfitters.

A booklet compiled by the Consumers' Gas Company of Toronto, for the use of architects, builders, owners, plumbers, and gasfitters, contains much useful information. In this it is pointed out that town gas, when burned in appliances which are properly designed, constructed, and installed, is a most economical and safe fuel for domestic and industrial purposes. The fact that 75 p.ct. of all the complaints of poor gas service are found to be due to piping which is too small, or which has been improperly installed, should convince anyone that the public interest demands that those responsible for the building of future houses should see to it that the gas-piping system is properly designed and installed. Interesting figures are given of the remarkable growth of the gas industry in Canada and the United States. In 1901, the production of gas was 101 million c.ft. In 1924 the output amounted to 420 millions.

The following items are extracted from the piping instructions given in the booklet:

General Piping Instructions.

In all houses, flats, or apartments the gas line from the meter to the kitchen should not be less than $\frac{3}{4}$ in. in diameter.

Riser pipes should be installed wherever possible in an inside partition, and should never be less than $\frac{3}{4}$ in. in diameter.

Pipes should be so run as to drain towards the gas meter.

Sags or traps should in no case be permitted.

Never use a union in concealed work. Properly-designed long screws or right and left couplings are permitted, but must be carefully installed.

Cellar lines should be hung from the ceiling.

In calculating the size of run necessary to supply a number of appliances, where the actual amount of gas to be used per hour is known, consult Table 1, when appliances are located at, or near, the end of a line, and the rate of gas consumed per hour is fairly accurately known.

Where a system of piping is to be installed, Table 2 will be found useful.

Outlets for illumination should project not more than $\frac{7}{8}$ in., or less than $\frac{5}{8}$ in., from the finished wall, and should be firmly secured at right angles to the wall.

Drop outlets for illumination should project from $1\frac{1}{2}$ in. to 2 in. below an unfinished ceiling, and not less than $\frac{3}{4}$ in., or more than 1 in., below a finished ceiling.

Openings for kitchen appliances should extend 3 in. above the floor-level, and be 2 in. clear of finished baseboard.

In large buildings, where foundation walls are of unusual thickness, a way should be provided for service pipe to pass through walls when these are being built. The preferable way would be to build a sleeve of iron or terra-cotta pipe in the wall at the point where the service is to enter the building.

Riser pipes should always be installed and openings provided, so that in case a stoppage should occur, from any cause, the pipe can be easily cleared.

Meters shall not be set in small unventilated places.

Always use fittings in making turns, do not bend pipe.

When pipes pass through heavy masonry walls, they must be encased; the gas pipe resting on the bottom of the casing pipe, with a clearance of $\frac{1}{2}$ in. on top.

All tests will be made with an air pressure of 6 lbs. per sq. in. on a spring gauge or 12 in. of mercury on a mercury gauge.

Water Heaters.

A separate and independent line should always be installed to supply an instantaneous water heater having a capacity of more than 140 c.ft. per hour.

The size of a horizontal run to supply an instantaneous water heater should never be less than the size of the opening from the heater, and preferably should be one size larger.

Dampers should not be installed in any flue connection.

Gas Fires.

For one fire and one opening in kitchen not less than $\frac{3}{4}$ in. pipe should be used.

Three fires and one range may be taken off a 1-in. pipe.

When more than three fires are taken off a kitchen run, the minimum size must be $1\frac{1}{4}$ in. pipe.

Not more than one fire opening should be allowed off a $\frac{3}{4}$-in. pipe.

Openings for fireplace appliances must not project more than 1 in. above the finished bottom of the fireplace, and must not be run closer than 6 in. from either of the finished sides or back of the fireplace.

Table 2.—*Piping Size Requirements.*

(When gas is used chiefly for lighting and for small appliances using gas for fuel; when outlets are located at many points in the building; and when the total amount of gas to be used is not accurately known, or may be subject to future change.)

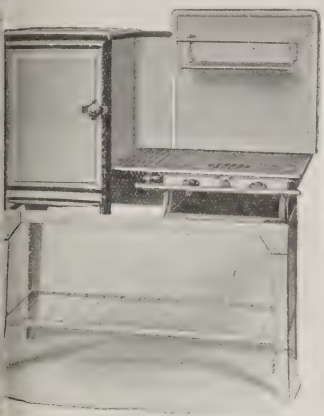
125	10	20	60	120	210	330	700	1200	1900	3,900
150	10	20	50	110	190	300	600	1100	1700	3,500
175	10	20	50	100	170	270	600	1000	1600	3,500
200	10	15	45	90	160	250	500	900	1400	3,000
250	10	15	40	80	140	230	460	800	1300	2,700
300	5	15	35	75	130	200	430	700	1200	2,400
350	5	10	35	70	120	190	390	700	1100	2,200
400	5	10	30	65	115	180	370	600	1000	2,100
450	5	10	30	60	100	170	350	600	1000	2,000
500	5	10	30	60	100	160	330	600	900	1,900

(Example: If the appliance consumes at the rate of 200 c.ft. per hour, and the length to be run is 100 ft., $1\frac{1}{2}$-in. pipe should be used, because 1-in. pipe, the next smaller size, will deliver only 130 c.ft. per hour.)

Association of Gas Salesmen (Northern Area).—Owing to the usual date of the meeting falling in Whit week this year, it has been arranged to hold the next gathering on Wednesday, June 10, at South Shields, by permission of the Management of the South Shields Gas Company. The following papers will be given: "Competition, Gas and Electricity," by Mr. T. J. Laycock (Tynemouth), and "A Few Remarks on Gas Appliances," by Mr. G. Lumley (Hull).

"Anti-Waste" Gas Cookers.

At No. 20, St. Paul's Churchyard, London, E.C. 4, Anti-Waste Appliances, Ltd., are exhibiting their cookers, radiators, water heaters, and what they term "combination sets," which comprise a kitchen range, gas stove, and hot-water supply. On entering the firm's showroom, one is impressed at once with the remarkably clean and well-finished ap-



An "Anti-Waste" Cooker—One of the Latest Designs.

pearance of the appliances. The main parts are finished in white enamel, and only require a cloth to keep them clean. Fittings are heavily nickel-plated, and these also only need occasional rubbing with a dry cloth or leather. The accompanying illustration serves to indicate the general appearance of these cookers better than a long description could.

Novel Features.

"Anti-Waste" cookers are fitted with a novel type of burner. There are two rates of gas supply at each tap, each having its own air supply, which can be regulated easily. The grilling burner consists of a straight cast-iron tube formed with a flat bottom portion provided with two rows of gas ports on each side. The tube can be rotated so that the flat portion faces upwards, thus converting it into a boiling burner. The oven is made of pressed sheet-steel, and the hotplate is provided with circular plates so that one can have a solid or open top at will. Other small and novel conveniences add to the selling power and flexibility of the cooker.

Result of an Exhaustive Test.

Some little time ago an "Anti-Waste" cooker was submitted to the Good Housekeeping Institute, of No. 49, Wellington Street, Strand, W.C. 2, for a thorough investigation. The cooker was used for the routine cooking of the Institute for four months; the work including baking of large rich fruit cakes, bread, biscuits, pastry of all kinds, and boiling, roasting, frying, and grilling, with highly satisfactory results.

The hotplate, state the Institute, is easy to keep clean, and saucepans do not tip-up. The discs for covering the boiling burners effect great economy, as two round or four square saucepans can be kept at boiling-point over one ring. The three-way turn of the gas-cocks is a convenience, as a steady simmering or boiling heat can be maintained.

The consumption of the burners, at a gas pressure of 2·6 in., is as follows:

Boiling burners, full on	20·4 c.ft.	per hour
Boiling burners, simmering flame	2·4	,, ,,
Griller	18·8	,, ,,
Oven	26·8	,, ,,

The efficiency of the boiling burners was found to range from 30 p.ct. to 41 p.ct., according to the speed of raising water to boiling-point. The former figure was obtained when one quart of water was raised from 62° to 211° Fahr. in 9½ minutes; the latter figure when the time taken for the same operation was 15 minutes.

The following specific tests were among those carried out:

Lunch cooked for ten persons, consisting of: Shepherds pie, roast beef, boiled potatoes, grilled tomatoes, steamed ginger pudding, Swiss roll, 3 doz. cherry cakes, and 2 doz. coconut pyramids.

Time alight	3 hours.
Temperature of oven in 20 minutes	440° Fahr.
Gas consumed	71 c.ft.
Cost at 3s. 7d. per 1000 c.ft.	3d. approximately.

Lunch cooked for twelve persons, consisting of: Roast pork, baked potatoes, greens, and trifle.

Time alight	2½ hours.
Gas consumed	72 c.ft.
Cost at 3s. 7d. per 1000 c.ft.	3d. approximately.

Lunch cooked for twelve persons, consisting of: Two meat pies, greens, potatoes, 4 doz. "Maids of Honour," and a large Madeira cake.

Time alight	2½ hours.
Gas consumed	85 c.ft.
Cost at 3s. 7d. per 1000 c.ft.	3½d. approximately.

Lunch cooked for twelve persons, consisting of: Roast beef, Yorkshire pudding, greens, baked potatoes, stewed rhubarb, custard, and two Swiss rolls.

Time alight	2 hours.
Gas consumed.	58 c.ft.
Temperature of oven in 20 minutes	440° Fahr.
Average temperature.	320° Fahr.
Cost at 3s. 7d. per 1000 c.ft.	2½d. approximately.

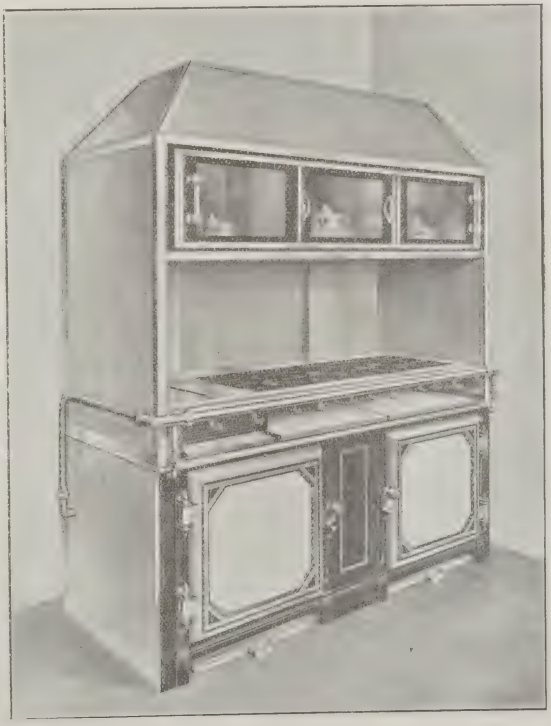
Gas Cooking in Large Mansions.

Even in such a prosaic sphere as the manufacture of gas cooking appliances, the rare gift of imagination is an asset. The owner of a large mansion near Hyde Park began to look round for a super cooking range worthy of being installed in his house. He was also the possessor of ideals which he did not disdain to apply to the equipment of his kitchen; and it was left to one of the Radiation firms, by means of enterprise and foresight, to turn his "vision" into the reality of an order, which resulted in the production of a gas cooking range worthy of the name bestowed upon it by its makers—the "Mansion" range.

This range, which is illustrated here, is made by Fletcher, Russell & Co., Ltd., and is an ideal cooker for the purpose for which it was designed. A short description may be of interest.

It is a double oven range, each oven being 24 in. wide by 24 in. deep inside, the hotplate being fitted with a grill and nine boiling burners of the "high-efficiency" pattern, with gas and air adjusters. The range has enamelled linings, enamelled trays under the hotplate, and enamelled panels in the oven doors. The whole of the range is highly finished, with all bright parts nickel-plated. A special canopy constructed of stout aluminium, and having sliding doors provided with plate glass panels, and highly polished inside and out, is fitted over the range, and encloses the hotplate. Special vent space is provided behind the hot closet, to prevent the entry of cooking vapours.

It may be stated that it is only in very special cases, such as the one just mentioned, that these superfine finishes are

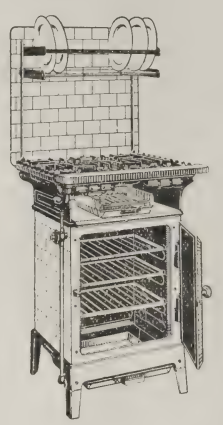


brought into use, as the efficiency and utility of a range are, of course, in no way dependent on high-class finish.

The kitchen in the mansion referred to is tiled in white-glazed tiles from floor to ceiling, and in addition to the range, all other appliances such as utensils, ice safes, china cabinets, sinks, water taps, &c., are in keeping. The addition of a highly-finished gas range completes an ideal kitchen.

Correction.—In Table V. in last month's instalment of "An Elementary Treatise on Gas Lighting," a slight error crept in. In item 3, sections *c*, *d* and *e*, B.Th.U. per candle-power-hour are on the basis of *mean hemispherical candle power*, the accepted abbreviation of which is m.h.s.c.p. The same, also, applies to source 5. The abbreviation m.h.c.p. in regard to these sources is incorrect. M.h.c.p. is the abbreviation for *mean horizontal candle power;* whereas the figures for inverted gas mantles and the petrol air-gas incandescent burners have been based on *mean hemispherical candle power*. The duty of the electric sources, except where otherwise stated, have been given in terms of mean horizontal candle power; and here the abbreviation m.h.c.p. is correct.

Window Display Technique.—Discussing the subject of window display technique as applied to the gas industry, Mr. E. T. M'Spadden, of the Public Service Company of Colorado, says, in the "Gas Age-Record," that everyone is artistically inclined to a certain extent; and therefore in presenting something beautiful one draws the interest of all who see it. The background itself of the window display should be one of two extremes. It should be very simple or very elaborate. The very simple is the better of the two, giving the appliance shown—he is referring particularly to the featuring of a single all-enamel gas range—every possible opportunity to speak for itself. In no other display does the placing of a floral piece or drapery to good advantage mean so much. The reading matter used in the window is worthy, too, of careful consideration. The public has had to endure for years the lengthy tale unfolded on cardboard, and for years has glanced at it and passed on. Why not try a short and to-the-point message in a dozen words?



Gas Salesmen are specially invited to send for the booklet describing the Radiation "NewWorld" Cooker.

Its automatic oven-heat control device is the most highly praised development in the Gas Industry since the Incandescent Lighting Mantle was produced.

EDITORIAL.

Cost of Inspection and Maintenance.

It is pleasing to note that systems of inspection and maintenance of consumers' appliances are being adopted in many places, and are giving satisfaction wherever applied. Where applied, that old complaint of "bad gas" is being forgotten; and people are learning that with the local gas good results can be obtained, if their appliances are kept in proper condition, and attention is periodically given to their regulation. To have conquered the lay theory of "bad gas" is a strong point in favour of the policy, but that is not the ultimate object. What we want to strive for is the highest possible contentment, for that has effective advertising power, and is the best inducement to the extended use of gas by the individual. We need not discuss the reasons for the adoption of the policy. They have had long existence. But they have become insistent; and we cannot understand gas suppliers resisting the inevitable, with, in view, business maintenance and progress.

Those gas salesmen who have read the report (published in our May issue) of the Southern (London Area) Circle will have been interested in the paper by Mr. J. Davis, of the Sutton Gas Company, and the discussion which followed. There are two or three points which strike us in connection with the proceedings which it may be profitable to emphasize. The first one is the unanimous favour to the policy shown throughout. There was no opposition; no one said it was wrong. Everybody knows that, no matter how faithfully the gas supplier looks after the interests of his concern up to the meter, all the good work may be negatived, and the hoped-for effects frustrated in the vital quarter, the other side of the measuring instrument, if the conditions for utilization are not correct. Small, medium size, and large undertakings are adopting the policy; and the testimony as to good effects is unanimous. We have Minehead (see "JOURNAL" for May 20, p. 530), with an output of only 48 million c.ft. a year, testifying to the advantages which result. We have the Sutton Company, with a very short experience, expressing through Mr. Davis gratification that they entered upon this work. We have Portsmouth wholly satisfied with their large experience in the matter. In Mr. Davis's paper, we see that it was only in November last that the Directors of the Sutton Company decided to initiate a form of combined survey and maintenance; and up to April 18, no less than 2393 gas appliances of different kinds (including 441 ordinary meters, 401 cookers, 796 fires, 570 burners, and smaller numbers of other appliances) had received attention. Also during that period a pleasing number of new appliances were sold or let on hire.

The point, however, that we wish particularly to make is that of the cost of doing this work. It must be borne in mind that in the initial stages—while the rough work is being done of weeding-out defects and putting appliances into good condition—the costs will be much heavier than they will be when that work has been accomplished. Take, for example, Sutton. Up to April 18, the expenditure was £68 3s., and the number of houses visited 441, which works out to approximately 3s. 1d. per consumer. This item in itself is not a serious one, seeing that, taking the average consumption per consumer per annum, Mr. Davis estimates that the cost is only approximately ½d. per therm sold. That fraction of a penny per therm to secure satisfaction is good expenditure, and is a small burden on the price of gas. The neglect of the expenditure might be eventually a serious burden on the undertaking. The displacing of inefficiency by efficiency is an economy for the consumers; and it is material defence of the interests of the proprietors of the concern. We have Mr. A. J. Garward in the discussion speaking of the cost of the work to date at Portsmouth. He says that it has averaged 2s. 2·89d.—that is, the cost of labour has been 1s. 11·5d., and cost of material 3·39d. The costs may be taken as being those of inaugurating the system in the respective circumstances; and we maintain that they are, in view of that, extremely low. The figures too will, as time passes, be materially reduced, in view of the fact that appliances once put in order will subsequently be easy to adjust and maintain in efficient condition. This point as to the reduction

of costs was well made by Mr. John W. M'Lusky in the paper he read before the North British Association earlier in the year, as mentioned in "THE GAS SALESMAN" for April (p. 80). In the case of Glasgow, the maintenance costs at the outset were estimated at 1½d. per 1000 c.ft.; but, at the time Mr. M'Lusky read the paper referred to, they had been reduced to 0·592d. per 1000 c.ft. Of this figure, he stated labour accounted for 0·375d.; material, 0·084d.; and overhead charges, 0·133d. Per therm the cost was 0·126d.—labour representing 0·08d.; material, 0·018d.; and overhead charges, 0·028d. Some undertakings have been deterred, through misconception as to the actual costs, from adopting the policy of inspection, adjustment, and maintenance of consumers' gas appliances. There is no doubt that experiences such as we allude to will help them to come to a politic decision in the matter.

Another point for determination is as to whether all appliances should be inspected and maintained at the same time, or whether they should receive seasonal attention. That is to say, whether lighting burners and gas-fires should be the subjects of inspection in the autumn, and probably again in mid-winter, while cookers and hot-water appliances should be the subjects of visitations in the spring. In our opinion, while the maintenance man is in the house, it would be better for him on the occasion of each visit to give oversight to the whole of the appliances. There is in these days no marked seasonal division in the use of gas appliances. Lighting burners are required all the year round—true to a less extent in the summer than in winter. Cookers, through their convenience and readiness for service, are also now utilized the year through. The same applies to water-heaters; and as to gas-fires we were thankful they were in existence some of the early mornings and during the evenings in the month of May. This climate of ours is doing something to make the valleys less deep in the load curve of the year.

Efficiency Tests.

IN all parts of the public service department of a gas undertaking there should be efficiency. Most administrators of gas undertakings are now mindful of the fact that it is highly necessary to do all they can to promote the efficiency of their sales staffs. Many of them, too, have excellently appointed showrooms; but we have noticed on more than one occasion allusions in discussions to the indifference that is sometimes shown to assuring that appliances exhibited in showrooms are of high efficiency. Where this applies, it is a great pity, because the showrooms of gas undertakings of all places should demonstrate good types of appliances. Moreover, unless there is assurance through tests that the appliances are the best that can be procured in respect of efficiency, the undertaking neglecting this duty is not rendering the best service to itself and its consumers. The point was raised in a paper which Mr. H. D. Madden read before a recent meeting of the Wales and Monmouthshire Institution of Gas Engineers (see "GAS JOURNAL" for June 10). In this he held—and rightly—that no gas-consuming apparatus should be shown or offered for sale unless it has first been tested and found eminently suitable and efficient in use with the gas supplied to the district. There will be general concurrence by gas salesmen that all types of appliances should be carefully tested under conditions of pressure with the actual gas provided, and that this should rigorously be kept to a standard calorific value and regular specific gravity and composition. Recognizing that it is possible to reduce to a negligible point the limits of deviation from predetermined gas values, the Cardiff Gas Company have arranged a physical laboratory wherein all domestic and industrial appliances are tested and scrupulously examined. There is an advantage in such a laboratory beyond that of testing and giving assurance that the appliances are of the right standard in respect of efficiency and structural fitness. That advantage is that it can also be utilized (as is the one at Cardiff) for giving the outdoor staff first-hand knowledge of the methods of testing and of the results obtained. Of course, the provision of laboratories for appliance-testing purposes is no new thing among many progressive gas undertakings. Such laboratories have long been established; and the benefits that have been derived are undeniable, especially as a means for certifying that a gas undertaking is in its purchases of appliances receiving good value for money, which value is passed on to the consumers of gas. We quite agree with Mr. Madden that salesmen should have to deal with nothing but good and efficient apparatus, and that all appliances should be eliminated which primarily may appear cheap, but are ultimately troublesome and inefficient, and thereby cause annovance and dissatisfaction among consumers.

Showrooms and Secondary Products.

THE main object of Mr. Madden's communication, to which reference is made in the preceding article, was to discuss ways and means whereby the value of showrooms could be developed. One way suggested was the promotion of the sales of secondary products, particularly coke and sulphate of ammonia. All gas salesmen know how important to a low net cost of gas into the holders is the maintenance of a good revenue from secondary products, and that the low net cost of gas is reflected in the charge to the consumers. Therefore the secondary products constitute a factor of great importance in the work of the gas salesman. Mr. Madden urges that showroom attendants should have imparted to them a good knowledge of the utilization of secondary products, and that there should be exhibits of graded coke and of sulphate of ammonia in the showrooms—thus utilizing this effective means of enlarging local sales. At Cardiff, the Company are in their various showrooms and offices exhibiting clean good coke, in graded sizes for all applications. The exhibits are in attractive form, with proper literature as to the use of coke ready to hand. It has been found that this method of propaganda does much to popularize and further the use of coke locally for domestic and industrial purposes; and, if carefully handled, Mr. Madden says the coke will compete with, and largely take the place of, anthracite for enclosed stoves and water-heating apparatus. The experience enables him to assert that this form of publicity is astonishingly effective; but he stresses the point that the showroom officials must be in possession of correct knowledge regarding the suitability and use of the graded sizes of coke, and be able to advise consumers accordingly.

With regard to sulphate of ammonia much the same may be said. Given a good exhibit and the necessary knowledge on the part of the showroom attendants, excellent results may be secured in the local sales of this product. The Cardiff Gas Company recently commenced to offer neutral dry sulphate of ammonia in 7-lb. linen bags with instructions for use printed on the back. Due prominence was given to the new enterprise in all the showrooms; and the result was that in a few weeks over 1500 individual sales were made, with, in addition, many inquiries, which represent potential custom. In other words, publicity brought this valuable fertilizer to the eye of the public; and they purchased sulphate locally. This work has also brought inquiries for quantities of one or two ton lots from small landholders many miles away. Also requests for further information and literature have come from a large radius—the applicants being mostly farmers and amateur gardeners who have awakened to the fact that gas companies produce a splendid fertilizer. There is also a good local field for the commodity in the form of lawn sand. This will find a ready sale in most towns and districts where there are large numbers of small grass lawns to residential properties. There is no question that local showrooms in the present day require studying with a view to developing their utility to the maximum degree.

The Largest Loaf.—In Minneapolis, where they make wheat into flour, a bakery has, according to the "Intercolonial Gas Journal of Canada," produced in a gas oven a loaf of bread 60 ft. long, and weighing 400 lbs., which is said to be the largest single loaf ever baked. Bakers have met the high cost of labour and materials by using improved methods to keep down the cost of bread. Old-fashioned coal or coke fired ovens, with uncertain heat, have been replaced by gas-fired travelling-hearth ovens, 100 ft. or more in length, in which a uniform heat of any desired degree can be accurately and automatically maintained. The same paper points out that it takes about as many bakers to furnish bread for the whole of the population of the United States as are required for the 2 million people of Paris. This is due to the use of the modern travelling gas-heated ovens by the wholesale bakeries of America. One of these travelling ovens operated by two bakers can turn-out more bread than can dozens of bakers using old methods.

Showroom Window Display at Derby.

[Photo. by Edgar Jones, A.M.I.Chem.E.

The accompanying photograph shows the window display of the Derby Gas Light and Coke Company which was arranged for the visit of the Institution of Gas Engineers to Derby on June 12. The window, as can be seen, was simply and artistically arranged to demonstrate the value of gas for cooking, heating, and lighting, and the service direct from the cooker to the table, with minimum amount of trouble on the part of the housewife.

The apparatus was supplied by Messrs. John Wright & Co., of Birmingham, and arranged by Mr. Keeley, District Representative. The china was loaned by the Royal Crown Derby Porcelain Company, whose works were visited by a large number of gas engineers.

The display has attracted a large amount of attention by its simplicity and neatness, and it is anticipated that a considerable amount of business will accrue from such a distinctive advertisement.

Hotel Apparatus.

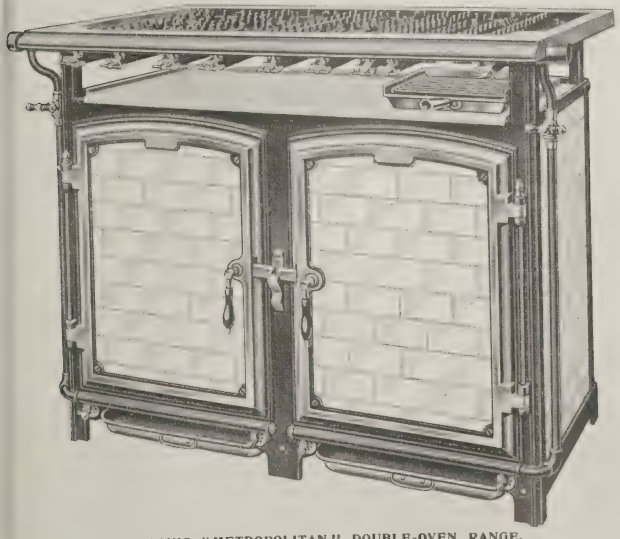
The white enamelled exterior, finished resemble glazed bricks, which is be- ming so familiar a sight on the domes- gas cooker, has been introduced by the avis Gas Stove Co., Ltd., in large cook- g appliances for hotels and restaurants. In their new catalogue, which contains most interesting pictorial selection of ieir improved large gas cooking appar- tus, the Davis Company thus present the ase for the cleanliness of gas in the hotel itchen: "It is well-known that one the many merits of gas-cooking, on ther a large or a small scale, is its eanliness. Gas is not only much cleaner use than solid fuel, but the absence of noke and dust encourages cleanliness in ie kitchen staff to a marked extent. In is booklet may be seen illustrations of avis gas-cooking appliances equipped xternally with white enamelled panels. ne cannot fail to be impressed by the icture of spotlessness presented by the itchens in which this apparatus is in- alled."

They have much also to say about the advantages of gas-cooking in hotels and restaurants, and they say it with admirable brevity. For this very reason the case gains so much in force that many a waverer into whose hands the booklet falls will find himself converted to a staunch belief in cooking by gas; and his decision will be confirmed by the neat, clean, and generally efficient appearance of the installations carried out by the Company, and illustrated in different parts of the catalogue.

Very few of us can remember the time before the "Metropolitan" oven was known to the gas industry. We are reminded in the booklet that it has been in existence for over forty years. In its up-to-date form, with white tile pattern exterior, and an improved type of hotplate, it occupies the premier position among the ranges in the catalogue. Though only double and treble oven sizes are actually listed, any practicable number of "Metropolitan" ovens can be ranged together under a continuous hotplate.

The series of Davis roasters, steamers, and hot-closets illustrated and fully described in the booklet represents a selection for all the ordinary purposes of large kitchens. Most of them have the clean white tile pattern finish, and all embody the most modern features.

There is no doubt that, apart from its value as a trade catalogue, the new Davis booklet will prove itself a valuable piece of propaganda for the increased use of gas by the large-scale caterer.



THE DAVIS "METROPOLITAN" DOUBLE-OVEN RANGE.

Gas for All Purposes at Margate.

In the "Bournemouth Daily Echo" for June 6 is an account of the many applications of gas at Margate, where, thanks to the enterprise of the Isle of Thanet Gas Light and Coke Company, gas is put to every conceivable use.

Hairdressers have adopted gas "curlers" for shingled locks in preference to electrical appliances. Carriage body builders are using gas driers; dairymen are using gas plant for sterilizing their bottles and in the preparation of pasteurized milk; self-ventilating gas fires have been fitted in hospital wards; bakers are using gas ovens; and confectioners employ gas for sugar-boiling processes. One enterprising trader has installed gas engines for the manufacture of huge quantities of ice cream, and uses his engines to work a miniature saw mill for a firewood business during the winter months. Dentists are using gas sterilizers, and photographers have installed gas drying apparatus for the inauguration of a new two hours' service and the development of amateurs' films and prints.

The lighthouse at the end of the Stone Pier has a gas installation. And the Trinity House leading mark for ships on the jetty shows a brilliant green beacon as testimony to the reliability of gas. A gas main has been laid at beach level, and bathing belles in the bungalow huts at Palm Bay bask in the warmth of gas fires whenever the sun forgets to shine. Church organs that suffered from colds and wheezes as a result of the non-warming properties of new electric light installations have been cured by gas heaters.

One of the most instructive examples of the rapid development of gas in relation to business at Margate is that of a local fried fish shop which has just been supplied with a special 3-in. main and 300-light meter to deal adequately with the daily "catch."

An Elementary Treatise on Gas Lighting.

For the Student Gas Salesman.

[COMMUNICATED.]

CHAPTER 10.

(Continued from p. 103.)

Having discussed the cost of the light as produced by different sources, we are now required to consider the equally important (but often neglected) question of quality. A source of light exhibits two principal features—intrinsic brilliancy and colour—and its standard of quality is assessed thereupon. As will be seen from Table 9, sources of light differ very widely in regard to their relative brightness or intrinsic brilliancy.

By far the most noteworthy point in connection with this table is the relatively small difference between the intrinsic brilliancy of ordinary luminous flames and that of the incandescent gas mantle, as compared with the enormous disparity between the brightness of flames and electric sources. The very great brilliancy of certain sources renders them, in their unshaded condition, "menacing from the oculist's standpoint."

As already mentioned, a measure of intrinsic brilliancy is obtained by dividing the candle-power of any light source by the area of the luminous surface; but "this quantity is very difficult to determine accurately, since, with the exception of the electric incandescent filament, no source of light is of uniform brightness over its entire surface; and for the sake of comparison we can only arrive at approximate values by assuming equal brightness over the generally effective lighting area of any radiant." (Bell.)

According to the late Dr. Louis Bell "the eye cannot comfortably endure a greater brilliancy in the source of light which is entering it, either directly or obliquely, than about 5 c.p. per sq. in. of lighting surface—*i.e.*, about the brightness of a petroleum lamp flame." There does not, however, appear unanimity of opinion among eye experts as to the maximum brightness that can be borne continuously without any physiological strain. While much lower intensities than 5 c.p. per sq. in. have been suggested, the contrary view has been expressed—that the eye is not seriously endangered by exposure to higher brilliancies. Those who state that values of the order of 2 to 3 c.p. per sq. in. ought not to be exceeded, presumably base their opinion on the fact that the average brightness of the sky is about 2·5 c.p. per sq. in. But a brightness of 10 c.p. per sq. in. does not seem to be unduly distressing to the eye, and in practice artificial light sources if subdued to 5 to 6 c.p. per sq. in. (an intensity which represents a reasonable standard for ordinary working purposes) are satisfactory as regards visual comfort. However, we can leave this controversial matter to those who are competent to argue the case, since it is the intention here merely to make the point that one of the good features of the incandescent gas mantle is its relatively low intrinsic brilliancy. Low intrinsic brilliancy is of great importance for the avoidance of eye fatigue; and a perusal of the values given in the above table at once reveals the marked superiority that gas possesses over electricity in this essential respect. The care of the eye should be carefully considered when deciding upon the type of light-source to employ; and (quoting from "Light and Illumination")* "one should therefore know something of the nature of this organ in order to understand why some lighting conditions are pleasant and others are the reverse." Fig. 135 is a diagram of the human eye. "The light first passes through an outer transparent layer, known as the cornea, then through the chamber behind, and the eye-lens, ultimately reaching the very delicate and sensitive layers on the retina, where the impression of light has its origin. This impression is despatched to the brain by the optic nerve. Now the retina has the power of adapting itself to light and darkness in a wonderful manner. Besides this, the pupil aperture of the eye acts as a safeguard (see figs. 136 and 137), opening to its fullest extent in comparative darkness so as to let in as much light as possible, but contracting in proportion to the brilliancy of the illumination so as to shut out excess of light. Partly by the alteration of the pupil aperture, and partly also by changes that take place in the retina, the eye can adapt itself to wide changes in the illumination; but the process of adaptation takes time, and is only possible within certain limits. If the eye is exposed to very sudden contrasts in brightness, or to a brilliancy so great that it cannot protect itself, the eye is bound to suffer. In many cases after staring at a bright source for a short time, and then transferring the gaze to a relatively dark background, one can see a bright 'after-image,' showing that the eye has been temporarily fatigued; and it takes some little time to return to its normal condition.† This effect is commonly described as 'glare'‡—the cause of which is the concentration of light over a small area and the degree of concentration, which is expressed in terms of candle-power per square inch of the radiating surface of the source, is what we mean by intrinsic brilliancy. Glare has to be cured; and it is one of the main purposes of globes, shades, and reflectors to prevent glare by softening and diffusing the highly-concentrated light of modern sources. Obviously, those high sources such as the tungsten arc (known commercially as the "Point-o'-Lite") and tungsten filament gasfilled lamp, which are, to their great disadvantage, possessed of very high intrinsic brilliancies, require much more attention in regard to curative treatment for glare than the vacuum metal-filament lamp; and the last-named needs screening to a greater extent than the incandescent gas-mantle, and so on in proportion to the fall in the brightness of the source.

Dr. Meredith Young,‡‡ in remarking that it may be taken as proved by physiological experiment that the human eye cannot admit with comfort a greater brilliancy of light than that of the Argand gas-burner or ordinary single-burner oil lamp, calls attention to the fact that (taking 5 c.p. per sq. in. as the degree of permissible brightness of a light-source "an upright incandescent gas mantle possesses an intrinsic brilliancy of about 20 c.p. per sq. in.—hence it needs a diffusing globe or distributing reflector, or frosted globe of about four times the area of the source, in order to reduce it to the required physiological amount. A carbon filament having an intrinsic brilliancy of (say) 400 c.p. per sq. in. would require a diffusing globe of about 80 times the area of the source to discount its excessive brightness; and metal filament lamps having intrinsic brilliancies varying from 600 (for the tantalum lamp) to 1000 (for the tungsten lamp) should, on the basis of the average brightness of 800 c.p. per sq.

* See "The Illuminating Engineer," Vol. V., December, 1921.

TABLE 9.—*Brightness or Intrinsic Brilliancy of Sources of Light.*

Source.	C.P. per Sq. In.
Sun	800,000 (A. P. Trotter)*
Searchlight, modern	400,000 "
Electric arc, naked	20,000 (J. Darch)†
Tungsten electric arc ("Point-o'-Lite")	12,900 (Dr. Thomas and D. Chandler)‡
Tungsten electric filament gasfilled lamp	5,250 (A. P. Trotter)
Flame arc	5,000 "
Nernst (zirconium electric filament) lamp	3,000 (Dr. L. Bell)§
Tungsten electric filament vacuum lamp	1,100 (Dr. Thomas and D. Chandler)
Carbon electric filament lamp	400 (average) "
Gas-mantle, high-pressure, inverted	250 "
Acetylene flame	60 (A. P. Trotter)
Gas-mantle, low-pressure, inverted	40 (Dr. Thomas and D. Chandler)
" " upright	23 (A. P. Trotter)
Frosted tungsten electric filament vacuum lamp	10 "
Argand gas flame	7·5 (Dr. Thomas and D. Chandler)
Petroleum lamp flame	4 to 9 (A. P. Trotter)
Batswing gas flame	3 to 4 "
Candle flame	2·5 "
Sky (average brightness)	2·3 (Dr. Thomas and D. Chandler)
Moon	2·0 "

* Taken from "Illuminating Engineering."
† Taken from "Trans. Roy. San. Inst.," Vol. XXXI., No. 10.
‡ Taken from "Illumination by Gas"—one of the World Power Conference Papers read in July, 1924.
§ Taken from "The Art of Illumination."
|| NOTE.—Presumably when burning 16 c.p. gas under the old illuminating power standard.

† Dr. Meredith Young ("Light and Sight") may be quoted as under in exemplification of this point:

"The intensity of the action of light on the retina can be demonstrated approximately (I do not put it at all high) by the production of fatigue or after-images. The thing can be easily tested (though in the case of the more brilliant lights the experiment is no pleasant one) by staring as steadily as possible at the source of light and then, in the darkness, finding out, by means of an assistant, the duration of the after-image. The image tends constantly to fade away, but a flicker or blink of the eyelids causes it to reappear very bright for the fraction of a moment. The image from a 50-c.p. Osram lamp is to my eye, at first yellowish, then reddish-yellow, then—somewhat suddenly—a beautiful violet, and this drifts gradually into black. The lighter colours usually have a dark halo, and the dark colours a light halo. Tested in this manner I found as the mean of a number of trials the following persistence of the after-image:

50 c.p. Osram lamp (new)	3 mins. 3 secs.
16 c.p. carbon filament (new)	1 " 45 "
Inverted incandescent gas burner	1 " 10 "
Wax candle (Price's), 16 to 1 lb.	33 "
Bryant and May's special (small) safety match	2 "

"It is important in any such trials that the eye be kept focussed as nearly as possible as it was when gazing at the light, otherwise it may be thought that the image has disappeared. I think these observations lend some support to the view that bright lights in the field of vision at all events help to induce exhaustion of the retina and eye-strain, and that the brighter such light the greater the exhaustion or strain likely to result."

‡ "The term 'glare' is perhaps a little difficult to define precisely, but it is now almost invariably used to describe conditions of excessive brilliancy such as are trying to the eye. The glaring effect in artificial lighting is almost always connected with the exposure of the eye to bright unscreened sources." [Gaster and Dow.]

‡‡ "Light and Sight," a paper read by Meredith Young, M.D., D.P.H., D.Sc., in October, 1913, on "Some Aspects of Scientific Illumination," at a conference held at the National Gas Congress and Exhibition, London.

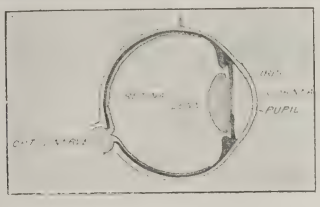


Fig. 135.

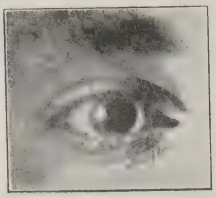

Fig. 136.—Pupil Aperture of Eye, wide open in the Darkness, so as to let in as much Light as Possible.

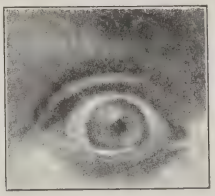

Fig. 137.—Pupil Aperture of Eye Contracted, so as to Shut Out Excess of Light.

in., be equipped with a diffusing globe at least 160 times the area of the lighting source." Reasoning along these lines, "Where," Dr. Young asks, "is the practical utility of creating such intensely bright sources of light when in the first place we have to handicap it down to the physiological limit, and when in the second place we are apt to run undesirable risks if the handicap is not what it ought to be?" Of course, neither unscreened filaments nor bare gas mantles should be used in positions where their rays can enter the eye either directly or obliquely; but the public are appallingly ignorant of, or indifferent to, this elementary requirement, as is evidenced by the numbers of dazzling sources which are placed in the direct line of vision without any attempt to discount their injurious brilliancy. It is unfortunately all too true that unshaded and inadequately diffused sources of excessive brightness are thoughtlessly located; and in these circumstances it is manifestly evident that in electric light we have an illuminant that is capable of much greater injury to the eye than gas light.

As one authority puts the case, "it is because the intrinsic brilliancy of the gas mantle is so low compared with that of the electric lamp that the light appears to be so much better diffused and altogether more suitable for the human eye."

"The eye is to some extent protected against injury from excessive stimulation by a physiological principle known as Fechner's Law. This is a law regulating the relation between the applied stimulus and the resulting sensational impression; and, stated generally, it is that the sensation does not increase in direct proportion to the stimulus, but only as the logarithm of the stimulus. Thus, if the applied stimulus be increased respectively 10, 100, and 1000 times, the resulting sensations will be only 1, 2, and 3 times greater respectively; and we probably realize but faintly how this wonderful physiological grading screens us from some of the blind sources of nature." (Dr. Young, *loc. cit.*)

Gaster and Dow, in urging the importance of avoiding glare when artificially lighting rooms, direct attention to the fact that the eye experiences a sense of weariness and fatigue when unscreened brilliant illuminants are placed in such positions that it is difficult for the eye to escape them, because the perception of such brilliant objects takes place through the formation of an intensely bright image on the retina; and consequently the effort of the retina and the photochemical pigment* to accommodate themselves to this extreme local brilliancy is very severe—sometimes impossible.

Dr. Meredith Young (*loc. cit.*) tells us that "eye strain does not cause any prominent symptoms in the eye itself; it is usually headache which is the chief symptom, and that headache may be in the forehead, the top of the cranium, or the back of the neck. One commonly observed peculiarity of this headache is that it disappears after a good night's rest, and remains away for some hours; but, if the patient resumes his ordinary occupation, it commences again pretty early in the day, and usually increases in intensity as the day wears on."

Miss M. Cleaves, M.D. (New York), in her work entitled "Light Energy," expresses the opinion that "there is no question but that the glare of unshaded electric lights is extremely bad for the eyes in house illumination; and not only discomfort, but impaired vision, results from their use." The opinion of another ophthalmic expert* reads as follows: "The electric arc-light should never be used for indoor illumination; it is too brilliant, too dazzling, and too concentrated. The naked filament or "wire-light" of the electric lamp gives an irregular shadowed field of illumination on the printed page or other near work. It should, in consequence, always be covered by a ground or porcelain glass when employed close at hand."

In this connection it must be remembered that the heavy screening of the filament here advocated can only result in the efficiency of the lamp being considerably reduced. In effect, therefore, the user pays for something he does not benefit by. He purchases electric energy to make light; but because of its excessive brilliancy a substantial proportion of the light produced is absorbed by diffusing glassware, in order to render the illuminant safe for the eye.

We are indebted to Dr. Young (*loc. cit.*) for further valuable evidence in regard to the care of the eye. Prominent among the many interesting opinions which he has so painstakingly collated there stands out the following "unequivocal opinion, from the point of view of eyesight preservation, in favour of gas-lighting, as given by Dr. Chas. A. Oliver, Ophthalmic Surgeon to the Wills Eye Hospital and the Philadelphia Hospital, U.S.A."

> "A superior grade of petroleum or mineral oil, unaided by any of the various forms of zirconium, thorium, and yttrium mantles, &c., gives a less concentrated and a less powerful, though more comfortable, working light than ordinary illuminating gas. Gas-light increased in power by any form of incandescent ash, though weaker in intensity than the malodorous compound of the two atoms each of carbon and hydrogen, known as ethene or acetylene, is, when properly diffused, much the more satisfactory and much the less harmful. The unshaded loop of electrical incandescent fibre and the naked arc of free electric fluid are the most powerful of all practical light-givers, possessing qualities which, if not removed, may lessen their usefulness as illuminants, and give rise to conditions under which prolonged near work cannot be maintained."

Another authority (Dr. Bell) calls attention to the fact that a flickering light will strain the eye seriously, and is likely to cause temporary, if not permanent, injury.

Gaster and Dow,* whose fairness is above impeachment, remark that "claims are not infrequently made for one or another illuminant that it is less trying to the eyes; but these are not infrequently of a vague and conflicting nature. One so often finds on examination that it is the manner in which the illuminant is used, rather than the quality of the light itself that is at fault. The statement so freely made at one time that electric light is bad for the eyes seems (so Messrs. Gaster and Dow say) to have originated rather in the misuse of the comparatively bright electric filaments, their exposure at close quarters without proper methods of shading, and the resultant glare, rather than in any defect in the quality of the light. But necessity—in this specific instance the necessity of removing the injurious glare of these very vivid filaments—ever the mother of invention, has done much to help forward the science and art of illumination; and the writer would indeed be ungenerous in thought and word were he here to refrain from placing on record the widely-acknowledged beneficial research undertaken by the electric lamp manufacturers in general and Messrs. Holophane, Ltd., and other illuminating engineers in particular in regard to the perfecting of a large series of standard globes, shades, and reflectors—a work in which all concerned may be justly proud." Here we must leave the question of intrinsic brilliancy, and direct our thoughts to the second factor governing the quality of an illuminant—viz., the colour of the light which a source emits.

* See "Modern Illuminants and Illuminating Engineering."

(To be continued.)

Better, Cheaper, and Brighter Cooking.—To be effective, advertising literature must be good. The Newcastle-upon-Tyne and Gateshead Gas Company have commenced another cookery campaign; and the literature which they are sending out to their consumers is in excellent taste. They point out that the woman in the home has sufficient trouble in planning and preparing over a thousand meals each year, without having unnecessary trouble with the cooking. The old way with the kitchen range means hours and hours of extra worry. Is it worth it, they ask, when for 1½d. a dinner for six persons can be cooked to perfection—with ease and to the minute—by gas?

* Mention of this photochemical pigment, termed visual purple (rhodopsin), involves a few words of explanation in regard to the chemical theory of vision. The view is held that this substance, present among the minute light-percipient organs (known as the rods and cones) situated, as it were, at the back of the retina, is decomposed under the action of light. Quoting from "Light and Sight" (Dr. Young) "this decomposition of the visual purple is now accepted as the causation of the sensation of light." In other words, light rays do not directly stimulate the termination of the optic nerve; but the visual purple is first decomposed or chemically changed by the light rays, and the decomposition products then effect the stimulation."

* Dr. Casey A. Wood—see his "System of Ophthalmic Therapeutics" (1909)—a work mentioned in Dr. Young's invaluable paper "Light and Sight," to which the reader is asked to refer for further information in regard to the care of the eye, &c.

B.C.G.A. Gas Salesmen's Circles.

Southern District—London Area.

The last meeting of the 1924-25 session of the Circle was held at No. 28, Grosvenor Gardens, Westminster, on June 2. Mr. Stephen Lacey, B.Sc., presided, and a paper on "Showrooms" was read by Mr. A. J. Privett, of Portsmouth. This resulted in a discussion which indicated the enthusiasm and interest of the members, and brought to a close a valuable session.

SHOWROOMS.

By A. J. Privett, of Portsmouth.

I have decided first of all to say something about window display and its general utility as an aid to business getting. I have decided upon this because it seems to me that some gas companies—not by any means all—do not make the best use of the window space at their disposal. They appear to fail to realize what an important part their windows play in the business.

To my mind the art of window display work is knowing how to create a greater demand for the gas appliances which we show in our windows. We ought also, as showroom people, to know how to prepare copy for showcards and window tickets, how to create atmosphere, how to attract attention, how to link-up window displays with circular and Press advertisements, and how to write "selling talk."

There are certain things which a salesman in a showroom always has in mind, such as the necessity for meeting consumers cheerfully, speaking correctly, and dressing neatly. So there are things which one must always bear in mind in window dressing, things which should come as second nature. To explain this more fully, I have taken the word "display," and have endeavoured to fit in words to help us to remember important things in window dressing.

D stands for something very important—decoration. All displays should take some form of decoration. You may not agree here; nevertheless I hold that it is essential. Such decoration need only be simple, but even then is attractive. A couple of palms, or a few artificial, or even real, flowers give the required finish to a window, and fill-in an otherwise empty space.

I for information. All windows should give some information as to the appliances on show. If we exhibit a cooker, and simply put the price on, this is information. In some instances more information must be given; but what there is, let it be right to the point.

S for suggestion. Windows should carry suggestions, more at some periods of the year than at others. For instance, at the end of the summer we should suggest, on nicely-written cards or in any other way which we think best, that the approach of autumn and winter reminds one that the time has arrived when gas fires should be installed. Make the home comfortable in readiness for the long cold winter evenings. Again, in the spring we might suggest that spring-cleaning time offers an excellent opportunity for putting in gas-fire supplies.

P for pleasing. Our windows should always be pleasing. It is rather difficult to say much concerning this, except to bring in colour whenever possible. Windows should be pleasing to the eye, because it is necessary to make a customer or a prospective one as happy as possible about the appliance which he or she is thinking of purchasing.

L for light. I think it hardly necessary for me to point out to you the merits of good lighting. We should know how to light our own windows to such an advantage as to create a desire in other shopkeepers for good lighting.

For window display work have good lighting. Well-lighted windows attract quicker than anything at night time.

A for attraction. We all know how very important attraction is in the window—important because it is the first step towards making a sale. We may have splendid appliances, but if nobody is attracted to them, they might just as well be packed in crates in the stores. While on this subject of attraction, I would like to point out the tremendous advantage of having a "live" window display such as a young lady working in a window arranged as a kitchen. The sight of someone actually at work in the window is always an attraction, and is a great aid to business getting.

The last letter in display is Y. This is an important letter because it stands for yourself. You cannot do any of these things I have mentioned unless you put yourself right into it. This is very necessary. If displays are to be outstanding, they should have a little of the display man's individuality about them. If we want to make our windows a success, we must put a bit of ourselves, a bit of our judgment, some thought, some of our ideals, into it; and then our windows will be a credit to us.

There is an important item which I would mention which could not be brought in in my use of the word display, and that is cleanliness. Do let us keep our windows clean. The glass itself should be kept clean, and in addition the floor of the window should be clean, and the appliances kept spic and span.

As showroom salesmen, we like to think that we sell the goods by our windows, but we must not overlook the fact that there are other means, such as Press advertising, circulars, "B.C.G.A." pamphlets, and the personal canvasser.

Why I have drawn a comparison between the window and other forms of advertising is because I do not think we fully realize what very valuable space our windows offer. It is the most valuable in the whole establishment.

We have heard much on the time that a window should be kept in. This is a very difficult proposition. I personally would not take-out a show within a week because we were not getting business from it directly. My contention is that, whatever you show, if shown well, you are educating the public, and therefore you cannot claim that last week's window is better than this week's. The window with the greatest capacity to sell appliances is the one which will sell this week, next week, next month, and next year, if needs be.

In my opinion, three great principles underlie window display:

1. The power to attract attention.
2. The power to create desire.
3. The power to stimulate action.

Dress the windows to strike the eye. If possible make a picture of them. Then the prospective consumer sees your picture, carries it away in his or her mind, or possibly comes into the showroom straight away.

You have created the attraction; and if your window is good you will get the desire following almost automatically. If you can get as far as the "desire" stage, you will without doubt have someone in to ask for further information. Then it is up to you as a salesman. Play up to the customers' emotions first, let them exercise their own judgment. Do not pester people. The day is gone for that sort of thing. Let them feel that they are deciding for themselves, yet at the same time work-in your own information as to usefulness, quality, efficiency, price, &c.

Showroom Management.

A very important point is the number of the staff. In this direction I think that gas companies fail in that the number is cut down to a minimum. This is a relic of the old monopolistic days. We are, perhaps, inclined to think that, as there is no other gas company in the particular town, people are bound to wait. This is bad business, especially when one thinks that if one goes into a small outfitters' shop there is usually a small army of assistants ready to wait upon one. So it should be with a gas undertaking's showroom. Let there be sufficient staff to attend to all customers without delay. Nothing is more annoying to a customer than having to wait for attention; and it is equally disquieting to the salesman who is busy with another customer.

Then there comes the question as to the efficiency of the staff. They should be capable of advising consumers upon the use of gas for any purpose whatsoever, able to explain the working of the various appliances in such a manner as to inspire confidence in the prospective buyer. In these days, too, it is of the utmost importance that they should also have a complete knowledge of electrical appliances.

Much has been said and written about showrooms' staffs as to whether or not they should be strictly practical people. Personally, I favour the commercially-trained man who has also laid himself out to gain all the information he can possibly get to assist him in his job. Many men, excellent men from a practical point of view, could not handle a prospective buyer to advantage, no matter how they tried. However, I should like to hear some opinions expressed on this point.

With regard to the stock shown, I am in favour of exhibiting as little as possible in the main showroom itself. If possible, a second room should be available for the display of the greater number of appliances. The main showroom should contain a few models carefully arranged, and, where possible, in a natural surrounding. Nothing is more galling than to see cookers and fires set-out in rows, like soldiers on parade.

Appliances should always be ticketed with a price ticket, so that people who may be walking round the showroom—possibly more or less out of curiosity—may be able to see for themselves the cost of a certain appliance. Of course there is something to be said for not pricing appliances. To have to inquire the price puts the salesman in the position of being able to talk, and may lead up to a useful sale.

A mistake is often made with regard to fittings hanging in a showroom. It is often so much easier to take a pendant or bracket from the stock room than to take it down from the showroom. However, if the appearance of the showroom is to be kept up to a high standard, when a fitting is sold it should be taken down, and a new one put up in its place. Provision should be made in all showrooms for the display of appliances in working order, so that

proper demonstration can be given. This can best be done by arranging (say) a bathroom and kitchen in suitable positions. In these, appliances such as a cooker, fire, wash-copper, sink water heater, circulator, and geyser can all be shown to advantage, and without any fear of overcrowding. This method is more pleasing to the eyes of intending buyers than a whole array of geysers or other appliances standing in line.

One has seen examples of a bad lay-out where the geyser fume pipes were many feet in length; and when five or six were displayed in one bathroom the effect was hideous. I have also in mind a display of no less than four sink and lavatory basin water heaters over one basin. The whole was confusing to gas men, so the effect upon the layman can well be imagined. So I would say again: Show appliances in working order by all means—in fact they must be shown—but let them be properly arranged.

In most modern buildings it has been arranged that consumers calling to pay accounts or to transact business in the office must pass through the showroom to get to the office. The utility of this method is best tested when accounts are coming in. Much more business is done, and it is easy to understand that people naturally look round the showroom. Then, if your showroom has been made to look interesting, and the appliances have been well set out, inquiries are almost bound to follow, with good sales as the result. Here again is an opportunity for a "live" show. During the period when accounts are being paid, considerable interest is aroused if a demonstrator can give (say) cookery demonstrations during the afternoon. The result accruing from such demonstrations is really surprising from the sales point of view, and, in addition, consumers are able to ask advice from the demonstrator upon points over which they had some difficulty. This alone brings about a friendly feeling between the consumer and the undertaking.

My next point to be dealt with is "complaints." Many are the views held on this subject; but whatever these views may be, and no matter how varied, everyone will agree that the subject of complaints is a very important one, and one which is growing in importance. It has been argued that the complaint gives the salesman an opportunity. In a few instances this is true; but as a whole I do not think that much business is picked-up by dealing with consumers' complaints. The ideal method, to my mind, is to have an intelligent junior in charge of a table or cash desk, such desk to be in a conspicuous position, and labelled "Complaints." At least 90 p.ct. of the complaints brought-in could be dealt with effectively at such a desk. Should there be anything in the remaining 10 p.ct. which called for higher knowledge than that of the junior, then let a competent member of the showroom staff deal with it.

However, whether this method or any other method be adopted, let it be worked in such a way that the consumer is not directed from pillar to post before obtaining satisfaction. The method for dealing with complaints which I have just suggested would, I feel sure, work very satisfactorily so far as the undertaking was concerned. Before passing on, though, I would like to point out what I consider the one stumbling block in such a system. Looking at it from the customer's point of view, a bad impression may be given by the fact that it is necessary to have a special desk and special clerk to deal with complaints. The thought would at once come into their minds that appliances, &c., must be in a very bad and inefficient state to warrant the setting-up of a special desk to receive complaints.

I think the time has gone by when one needed to urge that "B.C.G.A." literature should be used in showrooms. Everyone has realized what an asset this is; and I can only suggest that we go on using and distributing this literature for all we are worth. The effect is not always felt at once. Possibly the husband or wife of a family, or even the children, pick up a pamphlet, and nothing is thought about it at the moment; but in a day or two it is discovered in a coat pocket, and is read and re-read, with the result that business is done to the benefit of the undertaking.

When speaking just now about windows, I emphasized the need for keeping them clean. The same thing, of course, applies to the showroom itself and the goods or appliances. In view of the fact that many people labour under the impression that gas causes an excess of dirt, it is necessary to do all that is possible to destroy this impression, and to let people see that gas is the clean fuel which we hold it to be. Therefore the people who are employed to do the cleaning should be kept up to their job, and the whole showroom, including the appliances, should have an atmosphere of absolute cleanliness. Where woodwork other than a polished wood is employed in the structural features of the showroom, I suggest that the decoration be carried out in white, and the walls coloured with some light clean colouring. Not only will this give an impression of wholesomeness, but will also help to convince people using the showroom that gas is the cleanest fuel.

Again a consumer or prospective one will be dubious about installing gas fires on the ground that plants used for decorative purposes in the house are killed, or at least assume an unhealthy condition, when gas fires are used. From my own experience in the showroom, I have found that there are a number of palms and fern plants which will thrive in a gas showroom.

Not only does the use of plants help to persuade an otherwise dubious buyer of a gas fire, but the plants themselves are a decided asset in the decoration.

In the showroom at Portsmouth a convenient space is set aside where a table and one or two comfortable chairs are placed. Here people frequently sit and rest; and we like to encourage this sort of thing. We like people to feel that they are at liberty to walk in if they feel disposed without being pestered to buy. Incidentally the table which I mentioned has an abundant supply of "B.C.G.A." literature upon it; and people who sit at the table read, and by this means we have helped towards the great ideal of educating the public to the use of gas. The showroom should be homely, and of such a nature that people feel it a pleasure to come in and rest or walk round at liberty. Get them in, and get them interested, and inquiries will follow, with sales as a result.

Another very important point which concerns the showroom staff is the co-operation with the other departments of the undertaking; and here is a point where and why I favour the commercially-trained man. The man in the showroom should have a knowledge of the various methods of working in the office. It is said that the books must be accommodated to the business, and not the business to the books. This is very true. At the same time, if the showroom staff do not fully understand the "inside" methods, some wholesale blunders are likely to occur, and ill feeling often results. We are all spokes in a wheel, and one cannot get on without the other, so that co-operation in its fullest sense should be the order. While on the subject of co-operation, I would like to emphasize the need for this between the showroom manager and the buyer. In some undertakings the showroom manager buys the stock for his showroom. However, in many cases this is not so. It is up to the showroom manager to keep the buyer well posted in the type of appliance which is selling best or likely to sell best, due regard, of course, being paid to efficiency.

Discussion.

The CHAIRMAN remarked that they had all listened with interest to the paper. Mr. Privett had not said anything about the size of the showroom. It was often very difficult to arrange an effective display in a relatively small showroom window.

Mr. W. D. MEDCALF (Gas Light and Coke Company) said he would like to congratulate Mr. Privett on his paper, with the main points of which he (the speaker) was in sympathy. The underlying suggestion was the need for making their displays more effective. Perhaps he could best discuss the paper by telling them of one or two of the main principles employed by the Gas Light and Coke Company. First of all, it was desirable to avoid over-crowding. A spacious building was in itself impressive, and made the general public realize that the gas industry was very much alive, and was growing in strength. Secondly, his Company attempted to group apparatus. Instead of having a heterogeneous display of fires, cookers, geysers, &c., they had one section devoted exclusively to cookers, another to fires, and so on. It was their endeavour to have suitable surroundings for each appliance, so that customers could concentrate on one piece of apparatus at a time, instead of having their attention diverted by the close proximity of others. Cookers, for example, were isolated by being placed in a suitably tiled recess. As for fittings, it was advisable to arrange pendants on each side of the showroom ceiling, leaving the centre space free. By doing this, they had found that the selection of fittings by customers was greatly facilitated. Showroom windows certainly constituted a difficult problem. There should be no platform, and the window itself should not be higher than 18 in. from the ground. It was, of course, easy to talk of good display; it was a different matter to carry out their ideas in practice. He wondered whether they really knew what they wanted. Did they desire to base their displays on some particular apparatus, or did they wish to demonstrate what was meant by gas service? Often, suggested Mr. Medcalf, it was a good plan to have a folding screen as a background to a window display. This enabled them to have a centre exhibit and two wings; and, while giving sufficient background to lend a pleasing and co-ordinated appearance, it avoided the expense of an elaborate and permanent background. He did not agree that palms, &c., should be put in to fill up any odd space. Regarding the lighting of showroom windows, did Mr. Privett favour inside or outside lighting? He failed to see why appliances should be shown without price tickets attached. As for complaints, why should they use the word "complaints?" Surely "inquiries" gave a better impression. Mr. Privett had suggested that a junior could attend to complaints; but in his (the speaker's) opinion a junior had usually neither sufficient tact nor the necessary technical knowledge. The proper ventilation of a showroom was a very important point. The question of cleanliness—and every gas showroom must necessarily be spotlessly clean—brought to mind the vexed problem as to whether it was advisable to show appliances having a special finish. Personally he favoured the plan of demonstrating apparatus with a high finish. They were more easily cleaned, and gave the showroom a better and brighter appearance.

Mr. A. J. GARWOOD (Portsmouth) observed that he was in agreement with most of the points put forward in the paper. Mr. Privett had suggested that a showroom should be amply staffed, so that there was always a salesman ready to attend to a customer as he entered. A large staff was, of course, very desirable on a busy day; but on a wet day, for instance, when few customers called, some of the staff would have nothing to do. At Portsmouth they had encountered the difficulty by arranging for their outdoor canvassers to assist the ordinary showroom staff on busy days. Mr. Privett had also suggested that salesmen should have a knowledge of electrical appliances. In a country district, said Mr. Garwood, this knowledge should be extended to embrace apparatus for burning oil, which in outlying districts was still a hardy competitor, and one often difficult to displace. And then there was the question as to who was the best man to employ in the showrooms. Mr. Privett

favoured the commercially-trained man. He himself thought that practical training was an excellent asset. After all, this practical knowledge could be brought to bear on many of the inquiries received in the showrooms. Regarding price tickets, he had been impressed by a practice which he had seen in a showroom in the North of England, where they had tickets giving the running cost of fires, &c., per hour. A price ticket could with advantage contain, not merely the cost of an appliance, but also the hire-purchase terms, and some information relating to its use. It was essential to keep the showrooms clean; and he would mention particularly that all showroom ceilings should be free from dirt.

Mr. L. H. Holland (North Middlesex Gas Company) was of opinion that salesmen in the showrooms should have had practical experience on the district. He also thought that the principal types of apparatus should be on view in the main showroom, where in most cases the consumers paid their accounts. If there was a separate room for cookers, and another for fires, it often happened that customers failed to see the appliances exhibited. It was a good idea to have a separate place for receiving complaints, unless the staff was large, when they could be dealt with at a special counter in the showrooms. He had found by experience that highly-finished nickel-plated appliances were often more trouble than they were worth. Customers saw a cooker, for example, in the showrooms, but when supplied with a similar cooker with steel finish were dissatisfied, thinking they had got an inferior one. The question of affording adequate ventilation in the showroom was of first-rate importance. It was often difficult to avoid steamed windows.

A Member from Tottenham remarked that, at their meetings, and in their showroom windows, attention was given freely to consideration of geysers, cookers, fires, &c., but little regard had as yet been paid to the automatic washer, which had been on the market for many years. He thought there was a big field for this appliance. The electric washer was an expensive affair, and those who could afford to pay for it were the people who sent all their washing to the laundry.

Mr. J. C. Walker said he would like to refer to the question raised by Mr. Privett as to the type of man to employ in the showroom. Personally he sided with the author of the paper when it was suggested that the best man was the one trained commercially. He believed that one of the essential qualities of the showroom salesman or saleswoman was an engaging personality, as this undoubtedly appealed to consumers. The amount of technical knowledge required of the showroom staff could to a large extent be gained theoretically. Supposing there was a discussion in the showroom about a hot-water installation. Neither the practical man nor the theoretical salesman had any right to lay-down exactly how an appliance would work in any particular house, without having first seen the conditions under which the apparatus would be used; and the man to inspect these conditions was not the showroom attendant, but the outdoor man. Turning to the question of showroom window display, did they realize sufficiently the feminine element, and its bearing on business? Did they dress their windows with the object of pleasing the feminine or the masculine mind? He suggested that they should appeal more to women, and take into account the many little points which influenced a woman's choice. These little things mattered a great deal. There were often cases when women were more concerned about a burner "popping-back" when lighted, or whether gas fires tarnished silver, and so on, than about the efficiency of a hot-plate; and gas salesmen would do well to devote greater attention to these details. The appeal to the woman of to-day was saving of labour, cleanliness, and comfort. There was another point he would mention, and that was what he would term the luxury appeal of the modern showroom. They were apt, perhaps, to give an impression of luxury which was out of the reach of the ordinary consumer. There was no doubt that they could overdo the nickel and silver plating, the oak and mahogany panelling, &c., until the suggestion was made that gas was beyond the purse of many of their consumers. They could with advantage take note of the policy of furnishers, who set-up rooms of a given value. In the same way they should make a definite and strong appeal not only to the wealthier class of customer, but also to the smallest pre-payment consumer, bearing in mind that the latter represented no less than 30 p.ct. of the gas industry's business, and constituted, indeed, one of the mainstays of the industry.

Mr. Holland remarked that he had tried the effect of having a price ticket on every appliance in the showroom window, and also of leaving the apparatus unpriced, and only having showcards in the window. He had found the latter method preferable.

Mr. J. H. Johnson (Hampton Court) gave a few details of the management of a small showroom. It was the practice at Hampton Court, he said, to base their window displays on the selling of a particular appliance. As the result of a cooker display which remained in the showroom window for a week, they had received orders for 24 cookers. The outside lighting of the showroom was by low-pressure cluster lamps having a total candle-power of 3000; and the inside lighting was by similar lamps, which were concealed, and had a candle-power of 1000. By lighting the inside and outside lamps simultaneously, they could, after a short time, extinguish the inside lamps without fear of steamed windows. Regarding complaints, Mr. Johnson said that in his opinion these should not be received by juniors. The man who dealt with these should be experienced and intelligent, and should be able to look beyond the bare statement of a complaint to its possible cause. It had been suggested, both in the paper and in the discussion, that the showroom assistant should be commercially trained. He would go further than this, and say that outdoor canvassers should also be so trained.

Mr. C. F. Harford (Grays and Tilbury) remarked upon the employment of ladies in the showroom. A well-trained lady assistant was, he said, a fine asset. Commercially, they could be equal to a man. In their own showrooms a lady assistant had been with them for eight years, and they were very sorry indeed when she left, for her tactful methods of dealing with inquiries were of great value. As to the employment of "theoretical" or "practical" salesmen, it should be remembered that the outdoor man can always be asked for information and advice. Co-operation between the indoor and outdoor staff was always necessary. After all, no showroom attendant could give exact information about the working of an appliance in a particular house unless he knew the conditions which obtained in that house. He agreed with other speakers that the word "complaints" was unsuitable, and was apt to give the impression that complaints were concomitant with the use of gas.

Mr. W. Gaskin (British Commercial Gas Association) said he would like to touch upon the points raised by Mr. Privett regarding showroom window displays. Many suggestions had been made from time to time as to what they should, and what they should not, do. With the co-operation of members, the "B.C.G.A." were now in possession of some twenty ideas for window displays. These displays were available for the use of all members. Mr. Privett had raised the question of the time limit for a definite display. Figures proved that most displays began to lose attractive force after ten days, and that, except in special cases, the limit could be put at fourteen days. "Live" displays, of course, could with advantage run much longer than this; but even with these there was a limit. On the question of ventilation, Mr. Gaskin quoted the case of a showroom in the Midlands where there was a trench, 9 in. deep by 10 in. in width, running round the showroom. This trench was covered by thick layers of veneer to match the oak parquet floor, and contained gas supply pipes and also waste pipes. In this loose floor were inserted ventilating grids. Mr. Privett had spoken of the use of palms and ferns as decorations. There were, however, many other forms of decoration. Ribbons, curtains, &c., could be made to look very effective in a gas showroom. As could be seen in "Kodak" displays, and in the windows of Messrs. Lyons, the attractive scheme was an attraction *per se*, and had not necessarily any relation to the goods sold. This idea had been worked out to advantage in one of the displays made by the Portsmouth Gas Company, in which *crêpe* paper was arranged to represent the sun.

Mr. Harford mentioned that aerial photographs of the Grays and Tilbury area of supply had proved a decided attraction in the showroom window.

Mr. Sumner (Pinner Gas Company) was surprised to find that the larger companies seemed to prefer the commercially-trained showroom attendant. Of course, with large staffs it was possible to have practical as well as theoretical men; but the smaller concerns were limited in this respect, and he certainly considered the practical man as important and as useful as the theorist. As a matter of fact, both were indispensable.

Mr. W. L. Westbrook (Tottenham) observed that they needed more live displays in their showroom windows. Of course, many companies had to contend with old premises. When alterations were made, however, they should see that they had plenty of showroom space. For a medium-sized showroom, 50 sq. ft. was by no means too much. It was often an excellent plan to have a separate room devoted to demonstrations and lectures. Speaking of live displays—cookery exhibits, for example—it was necessary to fix carefully any apparatus, and make proper provision for dealing with products of combustion, &c. Waste pipes should be installed, and should, if possible, be concealed. He suggested that movable partitions could be used to advantage in a showroom window. It would thus be possible to have (say) a drawing room and a nursery or ironing room in one window. Whatever they did they should arouse the interest of their consumers. Much time and trouble could be saved if complaints were dealt with in an intelligent way, and proper inquiries were made as to the likely cause. When a fitter went to a house in order to remedy some fault, it should be his duty to inquire into the working of the other apparatus in the house. Practical training was necessary for showroom attendants, who should have both practical and commercial knowledge. Personally he would not trust a commercially-trained man to give an accurate estimate for an installation. If a salesman had no practical knowledge, he had to ask advice from one who had. In other words, two men were required where one should be sufficient. Salesmen should, for example, have a knowledge of building construction, and should be able to give proper advice.

Mr. Walker observed that the art of window dressing was a highly specialized one. Mr. Gaskin had mentioned the use of colour; and this was a big factor in catching the eye. It was necessary to make an impression quickly; and it should be borne in mind that their windows were in competition with others. This applied to all forms of advertising. Window displays were by no means easy to work out, and they should concentrate on something bright. The "B.C.G.A." would welcome the assistance and the ideas of everyone in the gas industry, and, indeed, would be glad of outside help and suggestions.

Mr. Bewsher (Brentford) remarked that gas companies did not train their assistants sufficiently in the art of window dressing. Generally speaking, he thought, salesmen were better than saleswomen, for it was seldom that a woman had sufficient technical knowledge, or sufficient patience and aptitude for learning technical facts, to make an all-round efficient showroom attendant. Regarding the staffing of showrooms, some undertakings seemed to overlook the fact that, having drawn the people into their showrooms by having attractive displays, they must have an adequate staff to deal with the increased number of customers. This problem was, of course, difficult, for people seemed to come to the showrooms intermittently in crowds. Co-operation must exist between the entire staff. When an undertaking purchased new apparatus, all members of the showrooms staff should be given full information as to its price and use. This plan was adopted with advantage at Brentford. They also had monthly conferences of the showrooms managers, and this also proved most helpful.

A Member asked Mr. Privett whether he displayed industrial appliances, and if so, what steps he took to relieve the monotony of the exhibits.

Mr. Privett, after expressing his appreciation of the manner in which his paper had been received, said that even in a small showroom it was possible to separate appliances which were let out on hire from those which were sold outright. At Portsmouth they had two branch showrooms, and were able to demonstrate a small kitchen and a bathroom. Referring to Mr. Lacey's remarks about a small showroom, he would say that, if care was taken, it was possible to make an effective display whatever the size of the showroom. Mr. Medcalf's scheme of grouping appliances was good. He (the speaker) hoped that this did not suggest crowding of cookers or fires; for it was desirable to show an appliance well, and give it plenty of space. If, for example, a cooker was placed in a model kitchen, far

more good would come of the display than would result from an exhibit consisting of a row of cookers. Speaking of the height of the showroom window from the ground, he would mention that the window at Portsmouth was necessarily higher than it should be. They had to decide whether their window display would be based on service or on appliances. Both bases were useful. In his opinion, what might be termed stunt shows did not pay from a sales point of view; and in most cases, in Portsmouth, they concentrated on displays exhibiting a particular appliance. In general, outside lighting of shop windows was at present condemned. Price tickets should be placed on appliances in the showroom; but it was often a good plan to have a few pieces of apparatus unpriced. When this was done, customers inquired the price, and gave the salesman an opportunity of effecting a sale. He was in agreement with the speakers who had suggested that "inquiries" was a better word to use than "complaints." He had mentioned in his paper that a junior could make a note of complaints. In a small showroom it was often a disadvantage for a salesman to have to leave a consumer while negotiating a sale, in order to attend to a report of an escape, or a request for burner regulation. Adequate ventilation of the showrooms was an absolute essential; and at Portsmouth they had a special plant for this purpose. They had no trouble at all from steamed windows. He was fully in agreement that showroom attendants should be commercially trained. Of course, the ideal was a combination of practical and commercial training. A salesman should certainly have sufficient technical knowledge to sell his appliances; but, after all, a salesman had no need to be a fitter. Even a practical man could not give an accurate estimate in the showroom unless he was fully aware of the conditions under which the appliance had to work; and this usually necessitated a visit to the consumer's premises. Mr. Holland had spoken of the finish of appliances. Personally he favoured a high finish, which was easily kept clean, and gave a pleasing appearance to the showroom. Much depended, however, on the neighbourhood in which the showroom was placed. Portsmouth was not an industrial centre, and consequently they had no need to show industrial appliances. The only possible demand was for sugar boilers and fish fryers. He agreed with Mr. Walker that they should appeal to the feminine mind, and that it was necessary to cater for the poorer consumer, who was apt to be overawed by the grandeur of some gas showrooms. The ideal was to provide universal attraction. At Portsmouth there was a display Association, in connection with which meetings were held every fortnight. He was a member of this Association, and he found the interchange of ideas very beneficial. It should, of course, be realized that window displays cost money; and gas undertakings must lay-down money to get a good return. He thought that it was very difficult to obtain suitable ladies for the showroom; usually they were not sufficiently interested in their work. At Portsmouth, however, they had a staff of ladies who interviewed consumers on the district in respect of cookers, offering advice and demonstrating how to obtain the best results from gas. They also had cookery demonstrations in their showrooms. Mention had also been made of the employment of backscreens. They should be careful when using them, to see that they did not detract attention from the appliances exhibited. Backscreens should always be subservient decorations. Mr. Privett said he was in entire agreement with Mr. Westbrook, who had referred to the fact that showroom staffs should be fully informed of any new apparatus which their undertakings intended to offer for sale.

The CHAIRMAN proposed a hearty vote of thanks to Mr. Privett.

This was accorded with acclamation.

Joint Meeting of the West Riding of Yorkshire Circle and the Lancashire District (Manchester Section) Circle.

A Joint Meeting was held at Leeds on Wednesday, June 10, when about 100 members visited the works of Messrs. Wilsons & Mathiesons. They were met by Mr. W. Mathieson, Mr. James W. Wilson, and other Directors of the firm.

SCOTCH FOUNDRY.

All departments were visited, showing the various processes from the pig iron to the finished casting. In the moulding shops various methods of moulding were demonstrated, including hand moulding from loose patterns and from plate patterns, also three methods of machine moulding, including the Company's own special type of roller moulding machine engaged on making various kinds of gas stove burners and other castings of a similar nature, as well as the latest American machine for the production of baths. The Company make their own porcelain enamel as applied to their "Swan White" porcelain baths. Enamel making was seen in progress, and the application of the enamel to baths. The working of the cupolas was explained.

Lunch was served at the Queen's Hotel, Leeds, at the invitation of the firm, after which the party proceeded to the Carlton Works, Armley.

CARLTON WORKS.

In the press shop huge presses were seen in operation, which stamp out the sides, frets, and backs for the "Sunbeam" fire. The assembling of this fire was next witnessed. The various component parts are fitted together very speedily.

A new electro-plating shop (which is twice as large and has twice the number of tanks as the old one) is now in full working order, and various plating processes, from the potash tank to the final lacquering, and specially fine samples of the work were viewed.

The polishing shop is fitted with powerful vacuum exhaust tubes for drawing away the dust. Another feature is the efficient natural ventilation whereby windows on both sides of the shop are allowed to open one-third of their area. The production of "Sunbeam" radiants is carried out, commencing from the raw material, which is conveyed by a shoot to a mixing mill, and eventually passes through a machine, coming out in a plastic brick-like form. These bricks are then cut into thin layers and placed in moulds with a core between, and are stamped to the required shape. "Thermo XX" radiants for the upright type of fire are similarly made. "Sunbeam" radiants are then blacked and stoved.

An interesting feature was the display of old gas appliances, including the first gas fire which was made by Mr. H. Wilson over 50 years ago, and a gas cooker 46 years old. The rapid strides made in gas fire construction since the days when these old fires were being marketted are remarkable, and the huge stocks of new fires ready for dispatch show the confidence the firm have in the continued demand for gas heating.

The new brass shop is ventilated similarly to the polishing shop previously mentioned. In this shop various brass fittings were being finished; and a special feature was the hot stampings which are used in place of castings, &c. These are handled with remarkable speed by capstans and other lathes; the perfectly formed and well-made fittings being turned out at the rate of 1000 per day. In the black-enamelling shop the visitors saw the prime coating of various component parts, a second coat by aero-spraying, and subsequent stoving in large coke-heated ovens. In the fitting shop the testing of metal thermostats for Wilson circulators was witnessed. Great care is observed in such tests, to enable every thermostat to be sent out perfectly calibrated, thus ensuring the success of this most useful contrivance. The making of the copper circulator, showing the necessary brazing processes, evoked much interest.

In the testing shop gas grate burners, both simplex and duplex, are tested under 24 in. water pressure for pin holes, &c., in the castings, so that absolute certainty is obtained that there is no escape of gas. The tap rails for the cookers, complete with the taps, are also tested under the same pressure as well as taps and injectors used on gas grates.

Proceeding by motor coaches to the Queen's Hotel, Leeds, the members were entertained at tea by Messrs. Wilsons & Mathiesons. Mr. W. Mathieson and Mr. James Wilson presided, and were supported by Messrs. S. H. Packer (Chairman of the West Riding Circle), P. H. Christian (Manchester Circle), C. E. Wilson, Walter Wilson, A. H. Jones, A. Gilson (Secretary of the Manchester Circle), and Mr. H. Wilde (Secretary of the West Riding Section). At the conclusion of tea the following address was given.

THE PSYCHOLOGY OF SALESMANSHIP.

"THE OTHER FELLOW AND MYSELF."

By A. H. JONES, Lecturer, "Education Section of Leeds" Psychotherapy Clinic.

A definition of psychology presents certain difficulties. A mathematical genius was once asked to give his opinion of this subject. There were a number of others in the room, but it did not deter him from making the attempt. He said, "Gentlemen, psychology is that subject which says, in language which no one understands, what everybody already knows." Whether or not this is true matters little just now. Psychology is certainly in agreement with the "intuitive wisdom of the human race." But as far as the language is concerned I am not going to attempt one of the usual methods of speakers on special subjects, and try to confound my audience with technical words. Rather would I attempt a brief review of what is understood by that word psychology, and whether it can be applied to the work which you are doing.

First of all, what does it mean? There are many meanings; but the best is that which defines psychology as the study of mental facts and phenomena. This is simple, and yet its scope, perhaps by reason of its simplicity, is extensive. You have very definite knowledge of your work—that is, of selling things. Of what use is psychology in selling? It can be looked at from many points of view. You have, perhaps, heard the story of the expert called in to mend a pump. He did so, and sent in his bill, which read: "To professional services, one guinea." It was sent back for explanation, and the answer came "To mending the pump, 1s.; to knowing how, £1." This, in all probability, represents the best definition of the difference between general knowledge and exact knowledge. For instance, most of us have ideas as to what is best for our own health, for our own well-being, and yet, on the whole, these ideas are only general, and it requires a little more than general knowledge "to know how" and to have sufficient confidence to charge one guinea for this knowledge.

It is to be understood, then, that psychology is the science of mental facts and phenomena. And what is its scope? Its scope at the present day seems to include a further understanding of most of the activities of every-day life—medicine, education, social organization, industry, advertising, salesmanship, the art of learning, of remembering, of forgetting—forgetting, by the way, is just as big an art as remembering, on occasions. It it covers aspects of those activities in general terms, what can it cover in more exact terms?

If one just examines its effect on industry—to take one, out of many possible subjects—one discovers that psychological investigation is throwing considerable light on the causes of fatigue. It is bringing an understanding of the various activities that go to make one's every-day life—of the various ideas and attitudes of mind, of emotions and feelings, of concentration on one's work. One finds that it is aiding advertising; that it is even aiding salesmanship. Those of you who have read what is, I believe, the latest book of Stephen Leacock, will remember his chapter on salesmanship. There he defines advertising in terms of modern American methods of psychology. You will probably remember one of his definitions, that advertising is the art of "arresting the human intelligence long enough to sell it something."

What value has psychology for salesmanship? I asked a question of a salesman in this way. "Do you believe that there is any psychology in salesmanship?" He said "No, there ain't no such thing. All you have to do is get to know the other fellow, find out his mood, discover whether he wants the thing you want him to have . . . . "—and he went on for about 15 minutes. He was then asked, "And what do you call that? What have you been doing? You have been describing the qualities, the ideas that are required to sell somebody something he may or may not want." He said: "I don't know. But it ain't psychology, anyhow." We left it at that, but some of those statements are worth looking at. Suppose the subject is discussed in four divisions. First one considers the article; next, the "other fellow," the customer; next, oneself, who is selling; and fourth, the interacting effects between the customer and oneself. The article is placed first. Presumably, one has some knowledge of that article. Yes, but how much knowledge?

How is one going to present that article? Is one going to describe it on its merits, or is one going to draw comparisons with other articles of a similar nature? This is sometimes rather dangerous! Undue exaggeration about any particular article is neither common-sense nor psychology, unless it happens to fit in with the demands or desires of any particular customer. Even then, it is a doubtful method. In fact, one is tempted to say that exaggerating the qualities of an article does not always bring belief to the mind of the customer. It may add 6d. to the salesman's commission; but this 6d. is being earned at the expense of his self-respect, and, instead of being placed to his credit, should really be placed on the debit side of his account.

Leaving the article, one approaches the aspect of the "other fellow." He is important whenever there is an opportunity of selling him something. This perhaps is another point where modern psychological research has helped considerably. First of all there is the growing knowledge of what makes the difference between types of customers. There is the very domineering type of man who comes in and wants to sweep the whole shop away as well as everybody in it. He requires special treatment, for he is going to have everything he wants in the way he wants; and if he does not get it, out he goes. There is the man who would rather go round by the back door than enter by the front, and who has to be persuaded. There is the individual, either a buyer or a seller, who would rather avoid going in either by the back or the front door; and if he can put down on his report "the people were out," it would give him intense satisfaction. Another type is most decisive, most deliberate; another always acts impulsively. There are psychological reasons for all these differences. They all require different methods of approach. But if one knows the why and wherefore——? The individual who said there was no such thing as a psychology of salesmanship had, however, learned from experience this one most important factor, that every potential customer is a special study, a special law unto himself.

There are some salesmen who are very successful in their own home district, but if they happen to be moved—if, for instance, they are brought from Kent to Lancashire or Yorkshire—they would find sometimes that those methods which were most successful in the South seem to "gang awry" in the North.

A certain firm once sent up a Londoner to Manchester. He was supposed to bring the same success into his work in Manchester that he had brought in the South. In three months he was recalled, because he had no capacity for making his own inner adjustments, to adapt himself to the different requirements of that particular district.

Now how can one deal with those various types? Suppose, to find an answer, one looks at oneself. Now psychology studies moods, feelings, and temperament, attitudes of mind, mental qualities, the cause of certain effects, conscious and unconscious processes. Take the case of a salesman going to his salesroom early in the morning. Suppose one has come down to work with the thought that one would rather be elsewhere. Is that going to have any effect on one's attitude towards work during the day? Or suppose an opposite case is taken, that which has the "little daily dose" feeling. The first state, in all probability, is going to induce irritation with the customers, because something has happened to oneself. The other one, providing his feeling is not too pronounced, will get on very well with the customer. And why? Is it the fault of the customer, or is the reason to be found within oneself? The question of success or fortune lies within oneself. For everyone who can do well can also do better.

One of the most important facts that follows is that which is called interest—especially the degree of interest that one has in one's particular work. This depends on whether work is a means to an end or an end point in itself. If it is a means to end, the interest is likely to be good. It will tend to bring in those psychological attitudes of mind—concentration, observation, attention—that control of emotion, that "something" which will enable one to give attention to detail which will bring about the desired result.

And what is the attitude of mind in general? There again many questions arise, such as inferiority or superiority in regard to types of customer, fear of losing one's position, or the desire to get higher. All these, either consciously or unconsciously, are going to have an influence in the quality of one's work. One always has a certain manner which is going to have its effect on the customer.

Now it may be of interest to have a look at some of the effects of these states of mind. Perhaps in modern times one of the greatest desires most people have is for security in some form. And this desire for security—a well-known psychological fact—is something that unconsciously influences one's conduct in a manner one can hardly realize. Some of its effect acts in this way. One is perhaps not quite sure of one's own knowledge and methods. One is perhaps not quite satisfied with the position one is holding, and yet one is sometimes afraid to take the necessary risk of making experiments. The fear may be the result of the desire for security. If one is prepared to take risks, especially "mental" risks, one finds the necessary courage and initiative.

One salesman, answering a question about the success he had had for a time, said this: "I've got a certain article to sell. I tell everybody it is absolutely the very best thing on the market." Turning round to his questioner, he said: "By the way, I was not sure it was the best, but at any rate I told everybody it was." So he had success up to a certain point, and then that success left him. The reason was to be found in that idea; his uncertainty had at last begun to dominate his mind. He never felt secure. He could not approach his work with confidence. His knowledge of the article was not thorough. As a result he failed. Another one, acting on knowledge gained through study and experience, observed his customers and studied each particular one. He was not satisfied until he had thought over the result of his daily experiences, and he succeeded. But it was only because he had, as it were, decided to take the risk and go on and learn the use of perseverance and suggestion; of aloofness and intimacy; when to be indifferent and when to show keenness. He did not, like the market salesmen, judge always by appearances. Assertiveness or submissiveness were put in their place, and did not dominate his character. For he discovered that customers are affected by the attitude of the salesman, and he discovered that he, if he were not careful, was easily affected by the attitude of the customer.

Now this study, which, through the medium of a talk and without the use of technical words, I have tried to describe suggestively, gives one an idea of the attitude of mind of the customer and oneself. It helps one to decide whether a line of approach is going to be the correct one in every case or is only suitable in a few cases. It brings up the point that submissiveness or enthusiasm carried too far induces intensity, and makes one lose grip of oneself and of one's work. Relaxation and rest and change are just as important in their place as the work itself. By understanding something of these various attitudes and feelings, one can discover how far one can go and what are the best methods to adopt for oneself. Then, one goes forward, and through study applied to experience, through experience applied to theory, continues the circle. Finally, one finds that in studying the subject, and then applying it to one's work, that the work has improved, and, at the same time, the knowledge of a subject has been gained.

Mr. Packer said he was privileged to extend to the members of the Manchester Section of gas salesmen a hearty welcome from the salesmen of the West Riding area. He felt that it was time the salesmen throughout the country became acquainted with each other in some other way, in addition to being introduced through that magnificent monthly paper the "Gas Salesman." If these combined meetings could be continued, success would favour them. They regretted that the Chairman of the Manchester Section, Mr. Sillitoe, the Secretary of the Manchester Gas Department, had been unable to be with them. They all knew how whole-heartedly and with what great enthusiasm he had thrown himself into this great movement for the benefit and development of gas salesmen throughout the country. His (the speaker's) second duty was to express some measure of appreciation to Messrs. Wilsons & Mathiesons for the magnificent way in which they had entertained and interested them that day. (Applause.)

They had with them two gentlemen, among

bers, who were an absolute credit to the gas dustry—Mr. Mathieson, the Chairman of essrs. Wilsons & Mathiesons, and Mr. James ilson.

Mr. Packer said that, as he went rough the foundry and the Carlton Works, felt that here, at any rate, was a great firm ho seemed ready from beginning to end to more interested in human beings than in ods. The time had come when only the firms ho could centre their general interest on the ople who worked for them would make headay in the commercial world. When this enomenal interest was combined with a high uality of production, and with extreme care the elimination of all faults in manufacre, then, he thought, they had got a firm ith the best qualities it was possible to have. He had pleasure in moving that their best thanks be given to Messrs. Wilsons & Mathiesons.

Mr. CHRISTIAN (Southport) said that the Lancashire Circle were at a disadvantage in the fact that their Chairman, Mr. Sillitoe, and their Vice-Chairman were unable to be present. Speaking on behalf of the Lancashire Circle, he thanked Mr. Packer for the cordial welcome. He also had great pleasure in seconding the vote of thanks to Messrs. Wilsons & Mathiesons for the very pleasant and particularly generous manner in which they had entertained them. They had thoroughly enjoyed the visit to the works. They had learnt many things, and to his mind one of the greatest assets of a salesman was to know thoroughly the apparatus which he offered for sale. Not only was it essential for him to know his customer, and to have that confidence about which Mr. Jones had spoken so ably, but it was essential to know the appliances.

Mr. MATHIESON, replying to the vote, said it had been a great pleasure to entertain the salesmen. Salesmen should have some knowledge of the manufacture of gas stoves, as well as their sale. Whatever they had learned by visiting the works would, he hoped, help them in their day-to-day work. Salesmen should have tact. It would be of great assistance to the manufacturers if they were acquainted of any complaints regarding their apparatus, so that they might investigate the cause. The firm of Wilsons & Mathiesons would welcome any complaints they might like to lodge.

Mr. WILSON also replied.

Southern District—Kent Area.

A Meeting of the Circle was held on hursday, April 23, at the offices of the unbridge Wells Gas Company—Mr. P. ickering presiding.

Mr. CHARLES F. CATT, the Secretary of he Tunbridge Wells Gas Company, informed the Circle that the Company were leased to have the members of the Circle s their guests. He said that his Chairman regretted his inability to attend.

The CHAIRMAN thanked Mr. Catt for his elcome and made a few remarks on the orthcoming Wembley meeting, saying hat he hoped a large number of the members of the Circle would be present.

EFFICIENT FITTING STAFF AS AN AID TO GAS SALES.

By ERNEST J. PENN, of Tunbridge Wells.

In introducing this subject, I propose to confine myself to the district fitters, as the training of these, to my mind, has been rather neglected in our industry.

Much importance has been attached to the improvement of the salesman, but too little attention has been given to the need for a well-trained staff of fitters. It is upon these employees that the success and reputation of a gas undertaking largely depends; and it is highly necessary that they should have a thorough knowledge of all fittings and appliances, and be capable of answering intelligently any questions concerning them, as lack of knowledge is often responsible for loss of business.

It must be remembered that a great number of consumers never pay a visit to the showrooms, and the fitters (with the exception of the meter inspectors) are the only employees of an undertaking with whom they come into personal contact. Who then has a better opportunity of pointing out the advantages of the use of gas, and the various appliances, than have the fitters? Something, therefore, should be done to give them the training that will enable them to give that service to the consumer which is so necessary to further the success of the industry.

Competition was never more keen than it is to-day, nor was the demand for excellence of workmanship greater; and it is most important, if we are to compete successfully with our competitors, that the standard of work employed should be of the highest. The best apparatus, whether for heating or lighting, can be robbed of many of its good qualities, and cannot be expected to give satisfactory results, if not properly fitted and adjusted; and we must bear in mind that it is where these unsatisfactory results repeatedly occur that our competitors are afforded an opportunity of creeping in.

Though the gas industry has made such rapid strides in the last few years, there still exists in the minds of some a prejudice to the use of gas; and a well-trained workman can do much to overcome this prejudice by making all work successful, and giving confidence and general satisfaction.

While working in a house a fitter may be approached by the consumer with reference to additional fittings or apparatus; and if he is able to satisfy the inquiries, instead of having to refer them to the showroom salesman, or to ask the inspector to call, he may there and then take an order which, for lack of immediate attention, may otherwise be lost. Complaints are often received which, upon investigation, are found to be due to apparatus or fittings that are old and worn out; and the fitter should be capable of pointing this out, and explaining the need for new appliances. In this way he not only lessens the number of complaints, but aids further sales and keeps the consumer's confidence, whereas repeated complaints tend to militate against the best interests of the gas undertaking.

Nothing is more detrimental to any undertaking's reputation than work which is faulty and badly done, while, on the other hand, a finished job which gives satisfaction stands first as an objective that leads to new business.

We need men who are efficient in all branches of fitting work. The custom of keeping one man for one job I consider is wrong, and occasions repeatedly arise when this is not practicable. This may be done if the size of the fitting staff permits; but a fitter should nevertheless have a good all-round knowledge, and be able to perform satisfactorily any job that he may be called upon to do.

We cannot, therefore, under-estimate the importance of giving to the fitting staff the training that is so necessary to further the interests of the industry; and the question now arises: "What can be done, or what is being done, to encourage the men to gain this knowledge?"

A good method, and one which is practised in some towns, is the holding of periodical meetings and discussions. This is particularly beneficial to the older fitters, as it enables them to become acquainted with the working of up-to-date apparatus. But we must not lose sight of the fact that the junior fitters and assistants of to-day are the fitters of to-morrow; and it is upon these that the progress in the future largely depends.

Some of the larger gas undertakings have made it compulsory that boys entering their service should attend classes of instruction in gas fitting, while others, in towns where there is a technical institute, have arranged evening classes for the benefit of their fitters. The latter system was adopted at Tunbridge Wells in 1923, and has so far proved very successful. From October until April two classes are held each week for instruction in the various branches of gas fitting; one lesson of two hours' duration being devoted to practical work, and the other, occupying one-and-a-half hours, for lectures and drawing.

This session 15 candidates enrolled, and the average attendance has been 13, thus showing that the interest and attendance have been well maintained. At the end of the session the students sit for the County Examination in Gas Fitting, and the following is the synopsis of the course of instruction:

Properties of Gas, and modes of distribution.

Governors.—Description of, and method of working.

Services.—Definition of, and sizes necessary for probable consumption.

Meters (ordinary and automatic).—Construction and working; points to be considered when fixing. Reading indices.

Gas Pipes and Fittings.—Uses of iron, lead and compo, copper and brass pipes and fittings; blown, screwed, and flanged joints.

Switch Lighting and Burners.—Description and construction of various types. Adjustments.

Gas Fires, Radiators, and Cookers.—Methods of fixing, regulation of gas and air.

Geysers.—Construction and working, methods of fixing, ventilating flues.

Gas Circulating Boilers and Thermostats.—Description and working. Methods of connecting to existing installations.

Ventilation.—Methods of ventilation by gas.

The foregoing will, perhaps, give some idea of the way in which the subject is treated.

Attendance at these classes is voluntary on the part of the men, but every encouragement is given to induce them to become proficient in their work.

The students' fees payable to the Technical Institute are paid by the Tunbridge Wells Gas Company, provided they register 80 p.ct. attendances, and sit for the examination.

I think you will agree that, if this matter was taken up more seriously by all gas undertakings, our industry generally would benefit greatly, and any extra expenditure that might be entailed for this important and very necessary instruction would be amply repaid by having more capable and efficient men around us, and the attainment of generally better results.

Tea was kindly provided by the Tunbridge Wells Gas Company.

It was decided to hold the first meeting of the next session at Dover.

Mr. PICKERING proposed a hearty vote of thanks to Mr. Penn for his paper, and also to Mr. Catt for all he had done to make the visit of the Circle a success.

Mr. KENNETT (Margate) seconded the proposition.

Mr. CATT and Mr. PENN responded to the vote of thanks.

Mr. WICKS proposed a vote of thanks to Mr. Pickering for presiding at the meeting, and also for his past services as Chairman of the Circle, pointing out that Mr. Pickering had carried out his duties in a most efficient manner.

The proposition was seconded by Mr. COLEMAN (Ramsgate), and carried unanimously.

Mr. PICKERING thanked the members for the support they had given him while in the chair.

The Secretary was also thanked.

Industrial Salesmen's Circle.

A meeting of the Circle was held at Birmingham on Friday, June 19.

During the morning about seventy members of the staffs of gas undertakings in this country visited the demonstration rooms and industrial research laboratories of the Birmingham Gas Department; the shops for the heat treatment of metals at the Windsor Street Gas Works; and also the works of the Moss Gear Company of Aston. The party had luncheon at the Imperial Hotel, and the afternoon was devoted to a consideration of brief technical papers of great practical interest.

The party were received at the Birmingham Council House by Mr. A. W. Smith, the General Manager and Secretary of the Birmingham Gas Department, who accorded to them a cordial welcome.

Demonstration Rooms.

In the demonstration rooms the party inspected a complete range of natural-draught gas heat-treatment furnaces of various makes, of which one or two were shown under fire; a gas and air-blast furnace for high-speed steel and general tool hardening; double and treble cased japanning stoves; jewellers' furnaces for melting, annealing, and enamelling; and a large number of low and high pressure gas-heated soldering-iron stoves. An oxy-coal-gas cutting machine was also demonstrated under practical conditions, together with a special form of furnace for the heat treatment of needles and similar steel articles without scaling.

Research Laboratories.

The visitors also inspected the main research laboratories at the Council House, including the strength of materials, the physical, and the mechanical testing laboratories, and the pyrometer testing and metallographical sections. Compression tests were conducted upon a 100-ton machine, and the party showed much interest in the various tensile, impact, hardness, and physical tests on material. A new method of hardening special tools was also outlined.

The Moss Gear Company.

After leaving the Windsor Street Gas-Works, where the heat-treatment shops claimed much attention, the party proceeded to the works of the Moss Gear Company. There they saw the heat treatment of motor gears being carried out on most scientific lines. All the heat-treatment shops are equipped with the latest types of gas-heated furnaces of the recuperator type. The work of this new form of recuperator was fully explained, and figures were given of gas consumption, showing a considerable improvement on the older furnaces.

Business Meeting.

At the afternoon meeting the chair was occupied by Mr. Stephen Lacey, B.Sc. (Chairman of the London Circle).

Mr. A. W. Smith observed that, though he had formally welcomed them to Birmingham, he desired again to say how delighted they of the Birmingham Gas Department were that the Circle were paying them this visit. Birmingham was often spoken of as "The city of a thousand trades;" and it was possibly because of its diverse trades that the Gas Department's attention had been focussed, more than in most undertakings, on the uses of gas for industrial processes. The industrial laboratories of the Gas Department had been in existence about sixteen years as a separate unit of their activities, but even prior to that, considerable valuable work had been done, particularly, of course, in the use of gas for motive power by their fittings department. The early experiments of the Department in the use of gas for industrial heating purposes proved that gas-fired furnaces could be economically used to a greater extent than had hitherto been done. Sixteen years ago many furnaces were crude; and gave comparatively poor results. It was recognized that greater headway could be made with furnaces designed and constructed on more scientific principles. New designs were accordingly prepared, and the Gas Committee decided to establish a separate section for pushing the sales of gas-fired furnaces and similar apparatus. A demonstration foundry and heat treatment shops were provided where furnaces of large capacity were demonstrated to interested manufacturers, and a separate showroom was established for the display of industrial apparatus. The success of this policy was almost immediately indicated in the increased quantity of gas which was used for industrial heating purposes. Like most industrial areas, they had, of course, their boom years during the war, and well over 30 p.ct. of their total gas was taken for heating purposes and motive power in industry in those years; the highest point being reached in the year ended March, 1919—namely, 35·12 p.ct. In the year ended March last 3541 million c.ft. were used for industrial purposes, being 27·98 p.ct. of their total consumption. In the design and development of the furnace side, it was found essential, continued Mr. Smith, to establish metallurgical laboratories to assist in solving the many problems which had to be overcome to meet the requirements of manufacturers. With those laboratories working in connection with the heat-treatment shops and foundry, a large amount of pioneer work had been done in the development of industrial heating plant suitable for dealing with the numerous processes carried on throughout the Department's area of supply, which covered not only the City of Birmingham itself, but the two large industrial Boroughs of Wednesbury and Darlaston. Their able Engineer in charge of that section of the activities (Dr. C. M. Walter) had no doubt given particulars of some of the typical problems they had been called upon to solve, including research work in connection with the heat treatment of steel used in the manufacture of aircraft and in many other directions. In fact, during the war the laboratories were almost the home of Government inspectors in connection with aircraft work, shell production, &c. The Birmingham Gas Department considered it an honour that their laboratories were recognized now by certain sections of the Air Ministry for the testing of materials used in connection with aircraft, and a considerable amount of work was carried out from time to time for other departments of the Government. The Board of Trade had granted permission for a special test mark to be used in connection with the certification of tests on materials carried out in the laboratories. Gas had been adopted by many local firms for the heat treatment of metals, including carburizing, hardening, tempering, annealing, as well as the melting of metals and alloys and the firing of enamels and ceramic ware. Mr. Smith apologized for the absence of the Lord Mayor (Alderman Bower), and the Chairman of the Gas Department (Alderman Lloyd). They asked him to say they hoped the Circle would have a successful and instructive meeting, and leave Birmingham with pleasant recollections of their visit. "There is no doubt in my mind," added Mr. Smith in conclusion, "that we have to look more than ever for future development of the gas industry to the cultivation of our industrial load; and though at the moment almost every undertaking in the country is faced with the necessity for increased prices, owing to a slaughtered residual market, this is but a passing phase, and it behoves us to work all the harder to increase the efficiency of the furnaces we are installing, and retain the goodwill of our consumers." (Applause.)

The Chairman said he was very interested to hear that 28 p.ct. of the total output in Birmingham was used for industrial purposes. This fact indicated the scope of the work, which was open to them all. He thought their visit to the industrial showrooms and the research laboratories would be a source of inspiration, and that they would return determined to make a renewed effort to increase their industrial load. With regard to the latter, they were looking to the heat-treatment of steel; and many of them were surprised to find that at the Moss Gear Company's works American tools

ere used. They were given to under- and that those high-speed tools could not made in England. He mentioned this atter to Dr. Walter, who had expressed e hope that in a short time they in his partment would be able to make those ols.

Dr. WALTER observed that the point had isen at the Moss Gear Works with re- ard to a special form of hob and gear tters for the machining of motor-car les. He thought it would be interesting them to know that they could without fficulty produce equally satisfactory re- lts in this country. Tools were being oduced in America in greater quantities an in this country; and their methods heat treatment were carried out on ghly scientific lines. They had an oppor- nity of witnessing a demonstration of e decalescent indicator, by means of hich could be determined the proper tem- eratures to which different grades of eels should be heated before being uenched for hardening. In America, ols of the kind under consideration were eat-treated by what was known as the ump method, which, in effect, was no- ing more than the application of the de- alescent indicator. Instead of worrying bout temperature and the like, they could ave the question to this sensitive instru- ent, which was claimed to be accurate to ithin 0·5 p.ct. The operator had simply o follow his record until the decalescent oint was reached, and then he knew that ne carbon in the steel had gone into solu- on, and proper results would be obtained y quenching. The matter was carried a tage further by the taking of micro- hotographs of the steel. Those were asted on the recorder chart, and the deca- escent point, or hump, as it was often alled, was traced over the micro-photo- raphs, so that one was thus able to find hat grain size was required for a particu- ar article. One simply picked out the oint upon the curve which corresponded o the photograph on which the curve was rawn; and the results could be repeated ith mathematical precision. Many of the ools from America had been treated by lectrical heating; but in Birmingham heir experience was that, with larger ools, the cost was too high. There was no doubt that the work could be done equally atisfactorily in this country.

SOME USES FOR GAS IN PRINTING WORKS.

By J. ENNALS.

In the time at my disposal it is impos- ible for me to touch upon all the numer- ous processes connected with the printing rade. For instance, I do not intend to deal with the production of pictures, pro- ess block making, and stereo-metal making and refining, each of which, in itself, would form a subject for a paper.

In London, so far as printing is con- cerned, our principal field lies in the pro- duction of newspapers and periodicals. Some provincial newspapers may not, at present, be ready to consider converting from solid to gaseous fuel, but it may interest you to know that the following London newspapers and periodicals use gas for melting stereo-metal in bulk—*i.e.*, in 7-ton metal pots: "The Times," "Daily Mail," "Daily Mirror," "Daily Telegraph," "Daily Chronicle," "Daily Express," "Morning Post," "Daily News," and "Punch."

A number of printers producing small periodicals also use gas for smaller pots.

In describing the processes, I will fol- low the various stages of production from compositor to the publishing or distri- buting department.

Lino. Slug Pot.—In this the ingots of stereo-metal, received from the foundry, as well as the used lines of type, or slugs, are melted and run-out into small ingot moulds, measuring about 4 in. by 2 in. These are a handy size for feeding the linotype machine, where the pot is com- paratively small, holding about 200 lbs. of metal.

Linotype Machine.—The linotype com- positor operator, working on a keyboard closely resembling that of a typewriter, sets-up the lines of type for the news columns. Picture-making is dealt with in another department, where gas rings and burning-in stoves are used in the produc- tion of zinc negative plates from the posi- tive photographic prints. The burner under the linotype machine metal pot uses about 12 to 15 c.ft. of gas per hour, and is controlled by a thermostat adjusted to operate at about 600° Fahr.

It may be well to mention here that one or two electrically-heated linotype metal pot heaters are now on the market—one I have seen is made by a French firm of manufacturers. The cost of this equip- ment, however, is high; somewhere in the region of £20, as against about £3 for the gas burner and thermostat.

A small jet plays on the throat or nozzle of the pot to prevent this becoming cor- roded with metal.

The made-up news lines are next set up in steel frames in page form, with or without picture blocks, as required. An impression is obtained by pressing or mangling wet papier mâché on to the type in the steel frame. This substance is known as flong, and consists of several thicknesses of specially-prepared paper pasted together to resist any tendency to crack.

Steam Heated Press.—The impression is then passed—still attached to the type setting—to a press, the under-side of which is heated by steam at a pressure of about 80 lbs. per sq. in. It is then allowed to dry down while still in contact with the type; the flong thus setting into what is known as a matrix, or mould. The older type of steam generator and press is self-contained; the steam genera- tor being fitted under the press. Gas- fired boilers, fitted away from the stereo room, capable of heating eight presses, are now superseding the older type.

Patching-up Hotplate.—The matrix at this stage has to be patched-up at the back with stiff pieces of cardboard to resist the pressure of metal while in the casting box, as described later. This patching-up is done on a hotplate about 3 ft. by 2 ft., heated by 3-bar bunsen burners.

Matrix Dryer.—When dry, instead of wet, papier mâché or flong is used, after the impression is made the matrix is placed in a matrix dryer to extract any degree of moisture, and to bake or fix the impression. The dryer has a rotating cylinder fitted inside, which revolves over 2-bar bunsen burners. The matrix is next placed in a chamber to preserve the half- round shape, and to keep it warm until it is required for the casting machine. Better castings are obtained by this pre- heating. The drying drum is rotated by a belt drive from shafting, or by a separate motor attached to the base.

Combined Auto-Plate Furnace and Cast- ing Machine.—This is our best "cus- tomer." The metal pot contains about 7 tons of stereo-metal, which is raised to a temperature of 640° Fahr., for casting operations. Usually more than one plate is made from each matrix, in case of damage either in transit or while the plate is actually on the printing machine. The weights of these plates vary according to the size of pages required. "The Times" plate is cast at 60 lbs., from which a tail weighing 20 lbs. is cut. This tail is neces- sary to ensure a good packing of the cast- ing box, with the result that a good plate is produced.

The plate, after having the edges cleaned-up, is next taken to the machine room ready for affixing to the rotary rollers on the printing press. A method of firing the furnace which has recently been found to be highly satisfactory is by the use of gas and air blast burners fixed hori- zontally to the pot, the flames impinging on a base of refractory material beneath it. This base becomes highly incandes- cent, and the heat is deflected evenly over the whole of the bottom. It is found that this is an improvement over the older method of vertical burners, with flames impinging directly on the pot.

Oxidation of metal and pitting of the pot is reduced to a minimum, since the flame does not actually make contact therein.

It is good to see that Mr. Brooks, the Gas Light & Coke Company's Technical Adviser, is with us, as he will probably be able to give us his opinion on both old and new methods, since he has installed both types for London daily newspapers. I think I can safely say that the new method has been found to be a distinct improvement. British Furnaces, Ltd., have also installed this type in several London newspaper foundries. The main burners are of ordi- nary town pressure gas, and air blast at about 1 lb. pressure, burning about 1200 c.ft. per hour when full-on for casting. Two or three natural-draught stand-by burners are fitted which are kept alight when casting is not being carried out, and which maintain a temperature of about 500° Fahr. These burners use from 150 to 180 c.ft. per hour.

It is common practice in London to keep these standy-by burners going all day until the casting begins for the next day's run. By this method the metal can quickly be raised from 500° to 640° Fahr. for casting, and the danger of cracking a pot is eliminated. The latter may result if the metal cools down sufficiently to form a hard crust at the top of the pot. The contents of the pot are never allowed to run below 7 tons. As plates are cast, used, or in some cases fresh, ingots are put in to replenish the molten metal.

The advantages of gas over solid fuel are many. For instance, between the editions of papers the whole of the bat- tery except the stand-by burners can be turned out. When solid fuel is used, it has to burn continuously and the metal also stands in danger of being overheated, unless carefully watched.

A new type of casting machine recently installed for the "Daily News" has a furnace capacity of only 2½ tons of metal, but is capable of casting at the rate of three plates a minute. The machine is made by Winker, of Berne, Switzerland; and we may hear more of this in the near future. The consumption on this machine is only 600 c.ft. per hour, when casting.

An important point when converting any solid fuel furnace to gas is to recon- struct the interior arrangement of brick- work between the outer casing and the pot, in order to restrict the passage of heat to the flue. An adjustable baffle should also be fitted to the flue vent, capable of being nearly—but not quite—closed when the furnace is "lying down," or when stand-by burners are in use. Much heat will be conserved in this way by a careful operator, who can soon become used to its manipulation. I stress these points as being likely to be deciding factors regard- ing the success of failure of an installa- tion.

Gas-heated Glue Pots are used in the machine room for various processes con- nected with the paper roll when starting up, making up, and patching.

Black or Metal Cleaning Pot.—In some print houses the used plates are run-down and cleaned-off in a black pot, so called because the ink is burnt-off in melting. Fresh ingots are cast from these for placing in the auto-plate, instead of feed- ing it with old plates in their dirty condi- tion. These "black pots" (ranging from one to three tons' capacity) are in most cases gas-fired by natural-draught burners.

Some smaller printers work with fur- naces of from one to three tons capacity, the latter having a pump feed to portable casting boxes, while with the 1-ton size

hand ladles are used instead. Many of these smaller type of furnaces are still fired by coal or coke.

By the installation of gas, floor space is saved. We were recently called in to substitute gas for coal for a 2-ton Hoe furnace in a printer's foundry. The conversion was satisfactorily carried out by natural-draught burners; and in the space formerly occupied by the coal bunker (about 8 ft. by 3 ft.) the printer was able to erect an extra machine to deal with the cleaning-up of the plates.

Monotype Machine.—This machine has a gas-fired metal pot very similar to that fitted to the linotype machine, and is used principally by trade typesetters, a good many of whom exist in and around the recognized printing areas of London and the larger cities.

The processes mentioned are the principal ones in which gas is used, but there are many other opportunities, among which I may add:

Rule-Casting Machine.—Job printers make a practice of casting their own rules or line spaces (flat metal strips) as and when required, since a great variety of thicknesses is needed. The rule-casting machine is capable, by adjustment, of producing, without delay, rules of any desired thickness, which is a matter of prime importance to the jobbing printer. The metal pot is heated by gas, as also is the delivery throat from which the cast rule is drawn. The delivery end of the throat is water cooled.

Type-Casting Machine.—This machine is also favoured by the jobbing printer, though it is sometimes found in the works of the larger publications. The object of this machine is to provide letters or characters of certain kinds of which the compositor is running short. A die of the character or letter required is placed in the machine, and type is produced at a rapid rate to make good the shortage. The metal pot is heated by a natural-draught burner. Ink ducts on "Wharfedale" and "Fleet" machines are warmed in winter, to ensure a good flow and to prevent the inking rollers from becoming too tacky. A method of carrying this out is to fix a saw-cut bar burner, with a low flame, at a distance of about 18 in. from the machine-board level, at the feed end. Experiments of this type were recently carried out a large London works, with highly satisfactory results, on machines printing cheques for most of the leading banks.

Hot Water for Hand Washing.—Machine-room hands, stereotypers, and compositors must be provided with facilities for washing, and the water must of necessity be hot. Gas water heaters of either the storage or instantaneous type should find a place in any well-equipped works. Many, indeed, are already in use; the reliability of the supply being greatly appreciated by the staffs employed.

Boiling Water for Tea Making.—As a good deal of the work in the production of a daily newspaper takes place at night between the hours of 10 p.m. and 4 a.m., when there are few facilities for liquid refreshment, provision is usually made for making tea on the premises, by the installation of gas-fired boiling water apparatus, for which there is a growing demand. The day staffs also have their needs attended to by the installation of grills and dinner-warming ovens.

I have not dealt with the processes connected with electrotyping and process block making for high-class illustrations, as space will not permit. This side of the business of printing is usually carried on by works which specialize in it, and should be dealt with in a separate paper.

The outstanding advantages of gas over solid fuel in the printing works are as follows: Cleanliness, ease of heat control, no man-handling of fuel or removal of ashes, saving of labour and floor space, speed with which first heats can be obtained, healthier working conditions, no danger of overheating metal, and no anxiety as to supply of fuel during transport strikes.

We in the gas industry have very good reason to feel justly proud in the knowledge that gas plays such a big part in the production of our daily papers. I have set out matters coming within my own knowledge, but should like to hear a discussion on the subject, and to gain further experience from others who have dealt with gas matters for printing and publishing firms.

Discussion.

Mr. B. W. BROOKS said that in London they were advocating low-pressure gas in preference to high-pressure. Where time was the chief factor, air-blast came in.

Mr. A. B. ROXBURGH (Newcastle-on-Tyne) inquired into the difference in consumption as between direct contact with the plate of the heating or refractory material.

Mr. BROOKS replied that, with the old-fashioned system, for every cubic foot of gas consumed, 4 lbs. of metal were cast; under the new system they had increased the quantity of metal cast to 6 lbs. per c.ft. of gas.

Mr. ENNALS said he had no actual figures as to cost, but on one London daily it was said that, all factors considered, gas was nearly as cheap as the solid fuel, but the great saving lay in the economy of floor space.

Mr. J. C. WALKER suggested that there should be a very big market for gas engines in printing works, where reliability was essential.

Mr. ENNALS remarked that though a general failure of electrical supply would bring a printing house to a standstill, some newspapers got their power from as many sources as was possible.

Mr. W. M. MASON ("B.C.G.A.") said the Glasgow Corporation Gas Department were able to keep the "Glasgow Herald" going during a coal strike. This was a valuable point from the publicity aspect.

Mr. E. L. OUGHTON (South Suburban) said there was difficulty in getting a good thermostat.

Mr. ENNALS pointed out that thermostats were supplied with the monotype and the linotype machines when they were set up.

THE APPLICATION OF GAS TO SHIP REPAIRING.

By J. M. LOUGHLAND.

The subject of my paper is a very big and important one, and the time at my disposal very short. My experience of this work on a large scale commenced when the British Commercial Gas Association advised my Company that Messrs. Harland & Wolff, Ltd., of Belfast, were about to erect extensive shops to be equipped for the repair, reconditioning, and redecorating of ships, lock gates, cranes, cold storage plants, &c., on a site adjacent to the commodious King George V. Dock, North Woolwich, which had just previously been opened by H.M. the King.

The London Manager at my first interview indicated that very little gas would be required, it having been arranged to carry out most of the heat-treatment processes with hard fuel or electricity. However, by persistent effort and the presentation of practical and instructive data, we were eventually able to convince his Company to such a degree that special plant was devised to carry out processes, which it is my pleasure to introduce to you today. Gas is supplied to these works by an 8-in. cast-iron main, passing through a wet meter of 40 therms per hour capacity, and is distributed by means of 8, 6, 4, 3, 2, and 1 in. supply pipes.

BOILER SHOP.

The most important process our special furnace department undertook was the heating of front-end and back-end boiler plates for flanging, which, as far as could be ascertained, had not previously been accomplished with town gas in this country. The plates naturally vary according to the size of boiler from 16 diameter down to 10 ft. diameter, from 1⅛ in. to ⅞ in. in thickness, and part to be flanged must be raised to temperature of 1500° Fahr., or bright heat. It is then placed in the hydrau press, and pushed over into shape.

The heating of these plates is done three distinct processes, and a furna had to be constructed for each of these

For furnace-openings and sludge hol the whole of the portion of plate to flanged is heated in one operation; in the case of the outer flange, which h to be bent in sections of about 6 ft., it w difficult to construct a suitable furnace, provision had to be made for that porti of the plate which is already par flanged.

The furnaces are constructed of hea angle iron with ¼ in. plate panels, a lined with Stourbridge firebricks. No. is heated by 51 gas and air-blast burner with separate control valves to sections 6 or 8 burners, for adjustment of flam and to cut out those not required for small plate; and the consumption is 12 therms per hour. No. 2 has 4 burner each separately controlled, with a co sumption of 7·5 therms per hour; and N 3 has 20 burners consuming 3·5 therm per hour. Gas is supplied at approx mately 4 in. water-column pressure, ar air-blast from Keith and Blackman No. "S" type high-pressure air blower 10 in. water-column. These furnace have so far proved to be very satisfactor and have many advantages over othe methods of heating the plates, which w previously carried out in hard fuel fu naces with forced draught. The temperature in all parts of our furnaces is unde control, which eliminates the risk of loc overheating, burning, and pitting plates, and underheating, with resultan splitting when bent in the hydraulic pres I regret it is not possible to give you som figures appertaining to the efficiency o these furnaces, as they have only recentl been installed, and we have not yet ha the opportunity of actually testing the in operation.

We also fixed in this shop five larg rivet heating furnaces, made by our cou sumers on the same principle as those used in one of their works. These are fitted with gas and air-blast burners and controls by British Furnaces, Ltd. The heating of rivets for any work is very im portant. A bad rivet in a boiler is a mos serious matter, and may lead to a bad accident if it has been burned, pitted, or scaled during the process of heating, and it has been proved by experience that the use of gas for this process obviates all dangers of this nature.

TINSMITHS SHOP.

Our furnace department also constructed a tinning bath furnace, fixed in the tinsmiths shop, for re-tinning copper cooking utensils usually used on big ships. We also fixed twelve Keith and Blackman high-pressure soldering-iron stoves, and converted a 100-gallon tank—previously heated by steam coil—containing caustic solution for cleaning of apparatus to be repaired. The heating of this tank by steam was unsatisfactory, as it was not possible to clean out the sludge which fell to the bottom around the coils. Natural-draught burners were fitted beneath this tank, with very satisfactory results.

COPPERSMITHS SHOP.

An 80-gallon bitumen cooker was installed in the coppersmiths shop, fitted with a hard fuel furnace, to be used for melting pitch to load large copper tubes before bending. It was pointed out that there would be a great loss of time in lighting-up a furnace of this character, particularly in an emergency job when the coppersmith had prepared a pipe for bending. With irregularity of temperature also, the pitch may burn, and great diffi-

y may be experienced in filling the pipe properly melting-out the pitch when bending had been accomplished. The antages being so great in favour of n gas, we obtained instructions to con- this apparatus. A natural-draught ner was fitted, and the ventilation red to get the highest possible effi- ıcy from the gas consumed. Blast vpipes for brazing were also fitted in shop, and have proved to be the best sible heating agent for this work, as t can be directed exactly where re- red, and the spelter made to run where ıted, resulting in a perfect braze. ıas-heated tanks, a copper, a sawdust ing pan in the platers shop, and two ge japanning ovens in the japanning p were fixed, all of which processes re re exact regulation of temperature, ily obtained by gas.

know you will be glad to learn that were able to render service to the elec- ians by fitting natural-draught solder- -iron stoves, and also burners for ing-out armatures.

ENGINEERS AND TOOL SHOP.

, Richmond oven furnace, 24 in. wide 9 in. high by 30 in. deep, and a John ight high-speed steel furnace with two umbers 8 in. by 8 in. by 8 in. were ed in the tool shop, for case-hardening, ıealing, and hardening tools, &c. They supplied with gas at approximately n., and air from a Keith Blackman wer at 8 in. water-column pressure, l are giving every satisfaction. Our nace department constructed a special -blast burner for expanding a liner in. in diameter by 20 ft. long by 1⅛ in. ck. It was so made that heat was ap- ed to the liner from inside; and, being table, the gas and air connections were de with armoured hose-pipe. In order t the burner may move freely at will, l the heat may be directed where re- ired, a wheel was fitted on the bottom, l a handle fixed 10 ft. long, made of n. barrel. The liner was set-up in a rizontal position in a cradle, and turned that the heat was evenly distributed. sting for the right temperature was ne by means of sticks of tinmen's solder, ich, when brought into contact with outside of the liner at the desired tem- rature, quickly melted. This liner was banded and shrunk on to a tail-end ppeller shaft under one hour, and the nsumption of gas was not quite 5 erms. From this experience it was de- led to alter the method; and the next e was set up on end in a pit, and heated means of natural-draught burners en- cling the outside of the liner every 2 ft. om the bottom. The metal readily took the heat; and therefore uniformity of stribution was accomplished. When the ıer was sufficiently expanded to take the aft, which, by the way, weighed about ght to ten tons, the latter was lowered to position by the travelling crane. This ethod was more satisfactory, and has en finally adopted. We also fixed a onometer metal-melting furnace for ating metal to run in bearings, and a rnace supplied by the same makers for covering metal from old electric cable d wire returned from ships. These are th giving satisfaction. In the foundry e fixed two powerful blast blowpipes ed by the moulders for drying purposes. here is no canteen in these works, but ree "C" type Jackson water heaters, ch with two taps, capable of supplying pints of boiling water per minute, were ted in different parts of the works to pply hot water for tea making. We are w making natural-draught burners to at a tank containing approximately 400 llons of caustic solution for cleaning linders and parts of engines to be re- ired.

CHAIN ANNEALING.

It is a Home Office Order that a re- ster must be kept of all crane and sling chains, lifting gear, &c., also that they should be periodically examined, annealed, and tested, as precaution against accident due to fracture. The method of carrying out the process of annealing chains, &c., in this country, is to build up the chains in layers of wood, which is fired, and the chains left to cool down in the ash, or to heat them in a wood-fired furnace. This was the practice at our Beckton Works, and crane chains of 1-in. rod link, 400 ft. long, took three men several days to anneal, as only portions of it could be dealt with at one time, and then it was a question as to whether every link had been properly heated.

A specially constructed gas furnace to carry out this process was made by our furnace department and fixed in these works. This will perfectly anneal a similar chain in six hours with the assistance of one man to see that it enters the furnace freely, and to guide and pack it into a steel tub when it leaves.

When the annealing is completed, the tub is covered up and left to cool down in its own heat. The furnace is fitted with a pulley, which is driven by a ¼ B.H.P. motor, to draw the chain through at the rate of just over 1 ft. per minute. It is also fitted with seven gas and air-blast burners, each separately controlled, and can be adjusted to the desired temperature and size of chain being dealt with. The burners are fixed in the top of the furnace, and the flame directed on to the floor. The products are drawn off through ports at the side, and thence into two flues. The consumption is 3·5 therms per hour full on.

Our Chief Mechanical Engineer informed me that this system, which has been used for two years, is very satisfactory, and much better than the previous process.

I regret that this paper does not contain more data as to the comparative cost of gas compared with other fuels, which I may have the opportunity of giving at some future date.

Discussion.

Mr. NOEL SMITH (Greenock) stated that in Greenock they had gone very deeply into the question of converting frame and angle furnaces from producer gas to town gas. At present, with the bottom out of the coke market, town gas would need to be sold at 4d. per therm to compete favourably with producer gas for this class of work. The Greenock price was 4·25d. per therm. Much better results would be obtained on a furnace specially designed for coal gas. Mr. Smith then put forward the following statement:

Comparative Cost of Working Frame Furnace on Producer Gas and Town Gas Based on an Output of 76 Tons of Steel per Week

PRODUCER GAS.	£	s.	d.
20 tons of coke at 27s. 6d. per ton (includes cartage)	27	10	0
Furnaceman, 47 ordinary hours and 24 hours' overtime	3	3	0
Assistant furnaceman, 36 ordinary hours at 10d. per hour	1	10	0
Discharging coke	0	17	0
Removing ashes	0	10	0
	£33	10	0

Cost per ton of steel, 8s. 9·78d.

TOWN GAS.	£	s.	d.
1927 therms at 4·25d. per therm or 470,000 c.ft. at 1s. 5·425d. per 1000 c.ft.	34	2	5
Furnaceman, 47 ordinary hours and 10 hours' overtime	2	10	0
	£36	12	5

Cost per ton of steel, 9s. 7·64d.

In arriving at the town gas figures, the temperature of 1800° Fahr. was assumed, with a throughput of 40 cwt. per hour. The gas consumption over one week (470,000 c.ft.) is based on the assumption that the furnace would require 6000 c.ft. during the first hour each morning to bring the furnace to working temperature. The actual working time during the week would be 38 hours; and at 40 cwt. per hour represents a weekly output of 76 tons.

Frame Furnace, 75 ft. by 2 ft. 9 in. by 1 ft. 9 in.	2000° Fahr.	1800° Fahr.
Holding at 2000° Fahr. =	1,750 c.ft. per hour	1,500 c.ft. per hour
Two 15-cwt. bars in 15 mins. =	8,500 c.ft.	7,500 c.ft.
From cold start in 3 hours =	45,000 c.ft. total	40,000 c.ft. total
Heating-up in mornings after previous day's work in 1 hour =	9,000 c.ft.	8,000 c.ft.

Conversion of Producer Gas Plate and Frame Furnaces to Town Gas Firing

	Frame Furnace.	Plate Furnace.
	£ s. d.	£ s. d.
Burner equipment, low-pressure system	509 0 0	270 0 0
Air blowing fan direct-coupled to electric motor, 250 v. D.C., complete with starting switch, &c.	115 0 0	115 0 0
Sundry materials	5 0 0	10 0 0
Labour	63 0 0	42 0 0
Pipeline and other sundries	98 0 0	51 0 0
	£790 0 0	£488 0 0

If high-pressure gas were available on the works, a saving of nearly £200 would be effected on the frame furnace, and £150 on the plate furnace.

From this statement it will be seen that, with coke at less than 30s. per ton (at the shipyards), and with gas at 4·25d. per therm, a conversion is not a practical proposition.

Comparison: Gas and Oil Rivet Furnaces.

	Twin Gas-Heated Furnace with Compressed Air Supply.	Open Feed Oil-Heated Furnace with Natural Draught.
Number of hours at work	8 hours	8 hours
Consumption of fuel	6400 c.ft.	48 gallons
Average consumption per hour	800 c.ft.	6 gallons
Cost of gas per hour at 2s. per 1000 c.ft.*	1s. 7d.	Average cost of oil per hour at 5d. gallon 2s. 6d.
Cost of compressed air per hour	3d.	"
Total cost per hour, gas and air	1s. 10d.	"
Average number of ⅝ in. diameter rivets, 3 in. long, heated per hour	500	200
Cost per 100 rivets	4d.	1s. 3d.

* 410 B.Th.U.

More efficient, cleaner, less danger of fire, furnace can be heated up in ten minutes—therefore unnecessary to bring in heater boy before starting time, as in case of oil furnaces—elimination of smoke, elimination of cost of cartage on oil and handling from store to furnace daily—these are among the advantages of gas.

From these figures it will be seen that there is no comparison between the open feed oil-heated furnace with natural draught and the gas-heated furnace. There is not, however, a big difference in actual fuel costs when comparing a modern forced-draught oil furnace with gas, but the over-all advantages are a long way in favour of gas.

Mr. W. M. MASON told the meeting that, as a consequence of sending to Messrs. Harland and Wolff the pamphlet "A Thousand-and-One Uses for Gas," an important inquiry came, resulting in special plant being advised to carry out a process at their new works. All depended on what was done with inquiries. Efficiently handled by efficient men with knowledge, business was bound to come after a time.

Dr. WALTER suggested that it should not be necessary to use air-blast burners in connection with the annealing of chains, as they at the Birmingham laboratories had obtained very satisfactory results with furnaces of the natural draught type, these being particularly suitable owing to the ease with which reducing atmospheres could be obtained in the furnace chamber.

LARGE PIPE BENDING.

By A. B. ROXBURGH.

I am not giving these few details respecting pipe bending in any way as the "best methods," but rather, if possible, to draw out, in discussion, ideas for doing the job better and more economically. Of course it is a trade largely carried out in connection with shipbuilding, and may not have so universal an application as have some other jobs. The pipes dealt with are usually solid drawn, and vary in diameter from 2½ in. to 8 in. Each works seem to have their own particular methods with apparatus that they have constructed for themselves.

It must be remembered that it is not altogether an easy matter to bend an 8-in. pipe to a complicated template, keeping it free from "kinks," drawholes, &c., and at the same time to maintain its full capacity and strength. The usual method is to heat the pipe for the required length in some form of furnace, and then bend it on a cast-iron holed table—the desired radius being obtained by means of iron pegs in correct holes in the table. The pipes, are, of course, first filled tightly with sand.

I was in a works last week where the method employed simply consisted of a blowpipe of home manufacture with a backing-up of firebricks to the pipe; the heating being done on the holed table itself. At some distant date they had constructed castings in holes, and lined with firebrick to encircle the pipe; the blowpipe being used through a suitable aperture. I suppose on account of the little trouble in fixing the arrangement, it had been discarded.

In another and much larger works, the foreman of the shop, who is a "live" man, has constructed a special furnace for each table, and the figures which follow may be of interest.

I may here interpose to remark how difficult it is in many cases to obtain accurate figures of everyday work. A test may have been made some time in the past, and the rest consists of impressions. It says something for ourselves, however, to state that, due to persuading them to adopt a better mixing of the gas and air, and thus shortening the flames, the gas consumption was reduced from 800,000 c.ft. over a period to 570,000 c.ft., and the work was accelerated.

In another large works they have no special furnaces, but just sheet iron sleeves lined with asbestos which they thread over the pipes to be bent. They have arranged gas and air supplies on each of the four sides of the tables for ease in working. No details of costs are kept.

The piping is generally used for high-pressure steam.

In one of the above works they have just solved another problem for themselves—

Results of Tests on Pipe-Heating Furnaces—October, 1924.

the brazing of copper from sheet to mal large-diameter (often 21 in.) exhaust pipe The metal is first roughly bent to t shape of a pipe, the edges are scarfe brought together, and then brazed—abo 12 in. at a time, until the whole length h been dealt with.

They use two slit burners applied to t underside of the pipe; the spelter and flu being fed in from the inside of the pipe on the top of the joint.

This is, of course, a special purpose jo but it is interesting as being one of th very many adaptations of gas to heating

Discussion.

Mr. BROOKS asked what was the thickne of the copper tubes; and Mr. ROXBURGH r plied that they were 3-16th plate.

Mr. NOEL SMITH asked if the web we heated externally. They had been told, h said, by a firm in his district, that a simil method to that described was not a succes It was found that the shafting became slight slack, and thereafter the method was adopte of putting the web into the oven.

Mr. SMITH, in regard to pipe bending, sai that a Greenock firm had replaced solid fu by oil; their contention being that the latte was cheaper.

Mr. ROXBURGH pointed out that wher work had to be done with an open furnace there was a great objection to the smell an smoke arising from oil. His contention wa that, on cost, gas beat oil, which was a fluc tuating market.

Mr. CAUDWELL pointed out that the autho had spoken merely of bending straight pipes How was a big curve to be dealt with?

Mr. ROXBURGH replied that the pipe woul be placed in the furnace with bricks packe around it. The pipes could be suspended a any angle.

Mr. MARSH then read a paper on "Ga for Power Purposes." This, with the dis cussion, will be published in the next issu of "THE GAS SALESMAN."

Lancashire District—Manchester Section.

A Meeting of the Circle was held at the Corporation Gas Furnace Demonstrating Rooms, Manchester, on Wednesday, May 27—Mr. J. B. Stewart (Rochdale), Vice-Chairman of the Circle, presiding.

An address was given by Mr. Shipley N. Brayshaw, M.I.Mech.E. (Manchester), on "Gas Furnaces."

Mr. STEWART said that Mr. Brayshaw was no stranger to the gas industry, and he (the speaker) considered they were fortunate in having him to speak on a subject full of interest. Gas furnaces played a very important part in industrial operations. Manufacturers were realizing that gas could show efficiencies far greater than any other fuel.

GAS FURNACES.

By S. N. BRAYSHAW, of Manchester.

Mr. Brayshaw began with some reminiscences of his experience with gas furnaces when he started business for himself in 1898. He then proceeded to speak of the accuracy required in the heat-treatment of tool steel; small differences sometimes having a vital influence upon the product. The lecturer advocated heating in liquids wherever possible, because there is a certainty in the process when a liquid is used, which is not attainable by any other means. In an open or oven furnace, you depend upon the judgment of the operator as to whether the work is at exactly the same temperature as the pyrometer; and sometimes the pyrometer reading may be very misleading, because it indicates its own temperature, which may be different from that of the work. On the other hand, if the pyrometer and the work are both in liquid which is kept sufficiently in motion by stirring, you can be sure that, after a short time, they are all at the one temperature, and the pyrometer truly shows the temperature of the work. If a piece of steel weighing 3 to 4 lbs. is cooled from a temperature of (say) 800° to 20° C., it will evidently take a very long time before it is uniformly at 20°; but if it is immersed in a liquid of 20° C., it soon reaches the desired temperature in every part. If the steel is to be heated from 20° to 800° C., the conditions are similar.

The lecturer spoke about the choice of liquid, and pointed out that its suitability is determined by specific gravity, conductivity, boiling-point, fluidity, and specific heat. He said he had tried lead and many other liquids, and advocated the use of suitable mixtures of salts.

Mr. Brayshaw gave some account of the hardening of high-speed steel, and sai that in this case he did not advocate heat ing in a liquid, because of the difficulty o doing so at the high temperature required He proceeded to speak of the injury don to metals through oxidation at a red heat and gave a demonstration of a brigh hardening furnace in which the work i heated to a good red heat in an atmo sphere of coal gas, and the arrangement are such that it is possible to dump the work into oil without its ever coming int contact with the air. After some piece of bright steel had been hardened by heat ing in the furnace and quenching in oil they were found to be as bright as whe they entered the furnace—indeed, it wa difficult to distinguish between the hardened and the unhardened pieces. A still more striking demonstration followe in which pieces which were black with oxidization were heated and hardened and they came out bright. It was ex plained that the coal gas reduced the oxide on the surface of the steel and left the bright iron. Pieces which were black when they entered the furnace were as bright as freshly-polished steel when they came out of the quenching tank.

Mr. Brayshaw showed a gas flow in dicator in connection with a furnace. In dicators are made of various capacities from 500 c.ft. up to 10,000 c.ft. per hour. The gas is made to pass through a throat of an exact diameter, and in the centre of

e throat is a small facing tube which re-ives the full force of the flow of gas, so at a small amount of the kinetic energy the gas is converted into static pressure. n order to eliminate the disturbing in-uence of varying pressure in the gas ain, a connection is taken at the side of ie throat. The two connections are then ken by small diameter pipes to the two des of a diaphragm in the indicator. Thus ie instrument consists of a differential essure gauge which balances the kinetic 'us the static pressure of gas against the static pressure alone. In this way the true kinetic pressure is obtained for a given velocity, as the gas passes through a throat of known size. Thus the velocity, and consequently the volume, may be calculated. The instrument is really a pressure gauge, but the readings show the corresponding flow of gas expressed in the most convenient form. The value of the instrument lies in the fact that the gas consumption as it changes from moment to moment can be seen at a glance without any calculation; and any irregularity in the furnace is discovered at once. In some cases these instruments are used instead of pyrometers, as it is found by practice that certain results can be obtained with definite gas consumptions.

Mr. P. H. Christian (Southport) moved a vote of thanks to Mr. Brayshaw, specially coupling with the vote the names of Mr. W. D. Gulland and his staff.

This motion was supported by Mr. T. E. Richmond (Blackburn), and was carried with acclamation.

Midlands Circle.

By invitation of the Chairman and Directors of the Leamington Priors Gas Company, the members of the Circle visited Leamington Spa on Wednesday, June 10.

The visitors were welcomed by Alderman Harold Mason, M.B., J.P. (Chairman of the Company), Dr. Haynes (Director), and Mr. R. S. Ramsden (General Manager and Engineer).

GAS AND GAS APPARATUS FOR DOMESTIC USE.

A perusal of a publication such as "The Ideal Home," especially in the advertisement portions, quickly convinces one that the trend of modern ideas is towards the reduction, and, as far as possible, the elimination, of some of the tedious and humdrum duties connected with the home. It is truly said that "a woman's work is never done," and it is not surprising, therefore, that the housewife of to-day should turn her thoughts towards a solution of the problem. That solution, as we all know, is to be found in gas.

Gas, properly and efficiently used, lessens the drudgery attendant upon the work in the home to-day. It rests with us to see that no effort is spared to bring this truth home to the public, and to acquaint them with the manifold uses to which our commodity can be put. We must hammer away unceasingly, striving to create that first vivid impression so necessary to ensure a lasting effect.

From continued observations due to constant daily touch with the public, it would appear that, while a large number are, to a certain extent, enlightened in respect of the uses of gas, there are still an appalling number not so well informed. The need for us to proclaim gas is more than ever pressing in such cases. The time has gone by when resting on our oars we can, with complacency, await orders. Our competitors are no longer content to let us have it all our own way, as in the past; and once we let them get in, it will possibly be no easy matter to get them out. Among other expressed reasons for the change-over is, I find, either an insufficient or an unreliable supply of gas, which brings me to my first point.

Supply Pipes.

We may classify this section under three heads—namely:

Past.—Buildings already piped.

Present.—Buildings in course of erection.

Future.—Buildings to be erected.

With regard to the first, we cannot, of course, do anything with the supplies already in. We have to put up with conditions such as are found; and it is here that we find ourselves paying for the practices of the past, when pipes were run without any particular thought being paid to possible future requirements. I dare say all of you can cite cases where orders have been turned down on account of either expense in renewing, or inconvenience of having new and proper-sized pipes run.

This, of course, more particularly applies where consumers are in residence. It is, as a rule, readily overcome in the case of a change in tenancy, when the work of running or renewing supply pipes can be done while the premises are in the hands of the decorators. Even in such premises we should keep an eye on the possible requirements of the future. If we have an order for (say) one fire, and the position runs adjacent to that of a possible future one, it is surely politic to see that the supply run will, if necessary, be ample for both. I know that in some districts this is done, but it might not be so in all cases; and while we are endeavouring to standardize gas apparatus, it might be well to consider the standardization of supply pipes. The point I wish to press is that we should endeavour to put in the maximum size supply, in order to save extra work and expense later on. This will greatly minimize complaints such as we now get regarding insufficient gas. We cannot always be wise before the event, but we can, and should, profit by the lessons of the past.

With regard to the second point, that of buildings in course of erection, we are here in a better position. In these cases the gas undertakings have previously been consulted in reference to the running of services, supply pipes, &c., and we may look forward to a healthier condition of things in general. In those cases where the carcassing of new houses is in the hands of the undertaking or their contractor, we can assume that the work will be carried out in an efficient manner; but should the work have been left to a local plumber, it is just as well to inspect the piping before it is covered up.

Regarding the third point, this is where we can, with the co-operation of architects and builders, so arrange matters that the installation of apparatus, either at the time the house is first occupied, or at some future date, will give every satisfaction in the matter of an adequate supply of gas. Here it is that, when given the opportunity of viewing the plans of the house, we can recommend really satisfactory supply pipes. I do not wish to weary you with specifications; but the tables due to Mr. Stephen Lacey, and published in the "Gas Salesman's Diary and Handbook," give the necessary information.

Lighting.

All will admit that competition as regards lighting is on the increase. The terms of many housing contracts now being decided are largely responsible for the change-over in Government houses; and in the case of those of a better type the architects and builders follow the lead given them—in goes the wiring, and potential users of gas for lighting purposes are lost. In many cases the desire of the occupant is never considered; otherwise I am convinced the result would be different. We know that gas is the cheaper, the light obtained is less harmful to the eyes, the ventilating properties are greater, and maintenance is less costly.

In what way can we combat this competition? We must first turn our attention to the enemy within our gates. I refer to the local ironmonger and other shops retailing so-called gas fittings. The insidious practice which has been going on for years, unchecked, of exposing for sale lengths of brass tubing, often with faulty and leaking ball joints and lever cocks, and which are misnamed pendants, together with the equally badly made brackets, and numerous inefficient burners and shoddy globes, must be fought until, by legislation, we can prevent the flooding of the market with these totally inefficient and unsuitable fittings. Very few of the public are able to discriminate between good and bad fittings; and as the latter are usually less costly, it is not difficult to understand how they find their way into houses. It is up to gas undertakings, therefore, to see that their fittings are beyond reproach.

A little demonstration in the adjustment of a burner is not only helpful, but is usually appreciated. It is better to do this than to take it for granted that the buyer understands all about it.

Much harm may be done by the wrong selection of a shade. How often does one meet the customer who wants (say) a red shade to illuminate the table and also give a good light round the room! A little tactful advice as to why such a shade will not fulfil the dual purpose results in the selection of a different colour, and the customer goes away feeling both pleased and satisfied.

There are two outstanding points which are always made the most of by our competitors—flexibility of control, and dirty ceilings. To the first we reply, "Pneumatic switches;" and though to a gas man they are simple enough, yet, to the general public, they appear to be elaborate pieces of mechanism. I think the cost of installation and the uncertainty of the pilot light militate against their use, and again I do not think they are pushed as much as they might be. Switches which we have had in use in the Birmingham showrooms for many years are still working satisfactorily; and it is an infrequent occurrence for anything to go wrong. Thousands of consumers use by-passes; and as no additional attention is necessary in the case of a switch, there is no reason why a greater number should not be installed. Possibly, as I have just mentioned, it is a question of price.

In connection with switches, it is recommended that where the tubing is let into the walls of buildings it should be run through lead piping, to counteract the action of the lime in the mortar.

With regard to the question of dirty ceilings; as the burning of gas must always necessarily be associated with heat, so must the discolouration of ceilings, more or less, be present where gas is used as an illuminant. We, however, know that the benefits derived where gas is the lighting agent more than compensate for the cost occasioned by the extra cleaning of the ceiling. Our competitors, while using this as a strong argument against gas, are careful not to mention the fact that the incandescent mantle, acting as a miniature sun, sheds a ray of soft light around the room, and the heat so generated causes an upward flow of air which

draws with it germ-carrying dust and organic impurities exhaled from the lungs and skin, cremating and depositing them on the ceiling, and thus sterilizing the air and making it far purer at breathing level than is the case where electricity is used.

I should like to stress the point that much can be done by both the indoor and outdoor staffs in assisting consumers in the economical use of gas for lighting by the judicious selection of the right size of burner. Unless the hall is a large one, a medium, or even bijou, burner will suffice, as will the latter for the landing, bathroom, and less important bedrooms. For principal bedrooms universal size burners should be fitted. In the scullery a medium burner will provide a good light for the gas cooker. The kitchen should have a full-size burner.

In the dining room or lounge, if brackets are also in use, a one-light pendant, preferably fitted with one of the cluster lights now becoming so popular, and suitably shaded, will provide, as a general rule, sufficient illumination for the dining table, or, in the case of the lounge, for the centre of the room. Much will, of course, depend on the size of the room; and local conditions must necessarily be taken into account. In the absence of switch lighting, I strongly advise by-passes to all burners where the periods of use are intermittent (except where they are unavoidably placed in draughty positions). The by-pass tubes require occasional attention, but the advantages accruing from their use easily outweigh their cost and the slight attention involved.

One more point. You regard competition in lighting as a sign of the times. Well and good. Has it ever struck you that manufacturers of lighting fittings and burners are themselves partly to blame for the change-over, by reason of their neglect to keep the public acquainted with the latest improvements? Commercial firms with goods to sell advertise their productions either by pamphlet or through the Press. Gas apparatus makers are doing splendid work, both for themselves and for us, in the advertising of cookers, fires, and hot water appliances; but where do you come across advertisements in regard to lighting fittings, except in trade catalogues, which the outside public never see? This point, to me at any rate, is a very important one, and I would like to see the "B.C.G.A." devoting a little more attention to this section of our supply. Their work in other spheres is invaluable; but I am convinced that, were the public acquainted with a few facts in regard to lighting, in the same way as they are provided with information regarding our other forms of activity, we should retain a good proportion of users of gas for illumination purposes.

COOKING.

Turning now to the question of cooking in the home, it may very truthfully be said that the gas cooker is the housewife's best friend.

As a labour-saving device, compared with the old solid fuel range, it is pre-eminent. It is far cleaner, more convenient, adds greatly to the comfort in the home, and is more economical. A turn of the tap, a light, and it is ready for use. The remarkable improvements which have been embodied in the present-day cooker, both in respect of design, cleanliness, and efficiency, are something of which the various makers may be justly proud. To-day we have a piece of apparatus which is good to look at, and which therefore finds additional favour in the eyes of the ladies; something which is easy to clean; and fitted with burners of an efficient type which are more economical in use than the old type with the attendant top bar which conducted the heat away from the point where it was required most.

The white enamelled sides and door do away with much labour. A wipe with a cloth is all that is needed.

The most fastidious customer can now be catered for in regard to a cooker. We have a variety of patterns from which to choose, all the same in a way, yet different, and it is here that the salesman can do an enormous amount of good for the industry in general, and his own undertaking in particular, by a careful inquiry into the wishes of his client before recommending any one particular piece of apparatus. Customers sometimes have peculiar ideas, and their likes and dislikes should be studied in order that the transaction may be satisfactory alike to the purchaser and the undertaking. Little differences should be pointed out; and it is often the case that such differences may coincide with their own ideas, and be the deciding factory in selection.

The eye-level type of cooker is a particular boon to many people who previously found the low position of the oven inconvenient. This type should always receive attention when the question of a cooker is being discussed. Unfortunately it requires a good deal of space to accommodate it, and the prices of some models are rather high. The "Standard" one-level is a most convenient type where space is limited, as the oven and hotplate can be fitted separately. There are also other makes which permit of this being done, and no difficulty need be found in meeting all conditions.

The neat white-enamelled topped stand comes in for many praises from the ladies, who appreciate the ease with which the space under the cooker can be cleaned.

There is an ever-increasing number of high-grade cookers being sold either outright or on hire-purchase terms in Birmingham. They are daily replacing those now installed on permanent hire; and it is seldom that one of the latter variety is ordered for new houses of the better type.

Other appliances, such as grillers, hotplates, &c., are frequently asked for. These can be supported either on stands made for the purpose, or on brackets. Whatever the type, the same remarks as regards adequate supply hold good. Nothing less than $\frac{3}{4}$ in. should be run. How often does one hear of decent-sized grillers and hotplates being fed from a bracket supply? It is important, too, when selling grillers, to give the fullest particulars as to the capacity of the apparatus. Some people expect to be able to cook a small joint in the oven, even in the type not provided with bottom burners; and much disappointment will be saved if the matter is thoroughly explained to the purchaser at the time.

Before I close this section of my paper, there are one or two points to which I should like to draw the makers' attention. They are taken at random, but have been the subject of complaints at one time or other. They are as follows:

Badly-Fitting Oven Doors.—In some cases several thicknesses of paper can be inserted between the door and its frame. Besides a loss of heat in the oven, this is a fruitful cause of rusting of the bright parts of the door.

Griller Burners.—Nothing is so objectionable as the smell caused by broken cones of the flame. Most griller burners now being fitted are of the "Roller" type, and cases have been found where the burner, when revolved to the grilling position, instead of remaining fixed, has a decided tendency to swing back.

Badly Spaced Burners.—In order that large kettles and saucepans may be used, sufficient room should exist between the burners. In a small hotplate this may be somewhat difficult, but it is a point which should not be lost sight of.

Oven Linings.—I suggest plain green or grey, not mottled. The former are more easily cleaned on account of their smoother surface.

HEATING.

The gas fire is to-day one of our biggest assets. This is not to be wondered at when we consider that for intermittent use, or service up to five or six hours' duration, gas is as cheap as coal, taking labour into consideration. Medical men are in increasing numbers are installing them in their homes, and in consulting and waiting rooms, and, further, are wholeheartedly recommending them to their patients. What better testimony could we have?

Architects and builders, though not helping as much in the matter of lighting, are certainly our friends when it comes to heating. Architects and others concerned in the building of new houses are being catered for specially by the introduction of the gas fire interior. These interiors are being made in many attractive designs and sizes, and are rapidly replacing the coal grates in bedrooms. Thousands of new houses have been so fitted, and we look forward to the day when they become standard practice. They not only affect a reduction in building costs, but—what is more important from our point of view—ensure the use of a gas fire, with consequent increase in consumption.

Another model of interest to builders is the "Teale" fire, the fitting of which enables the owner to have either a gas or a coal fire at will. The transition from one to the other takes but a few seconds.

A good gas fire, properly installed, advertises itself. It is up to us, therefore, to see that those we supply are the best obtainable, in regard to both design and efficiency, and that the fixing is carried out in a way that will give satisfaction to the consumer.

Once again I should like to emphasize the importance of an adequate supply. I can conceive of nothing more likely to cause irritation and annoyance to a consumer than, after delaying the event on account of some possible doubt, to have a gas fire installed, only to find it practically useless on account of a poor supply. It may be the pipes; it may be that the meter will not stand up to the additional call. In Birmingham due allowance is now made for increased consumption of this kind by fixing a larger meter free of cost. This will undoubtedly prevent future complaints regarding poor supplies.

I should like incidentally to remark that in dealing with defective supplies generally where the cause is due to local stoppages, we now clear these at a nominal charge. This is proving a boon in hundreds of cases, and besides improving our relations with the consumer by enabling his appliances to function as they should, is resulting in an increased consumption of gas.

The old type of fire and method of fixing once in vogue did much to account for the tale of the "Bowl of Water." Many people to-day judge the present-day fire from the same standpoint. Customs die hard. Don't let a faulty chimney be the cause of a revival of the "Bowl of Water" question.

As appearance counts for a great deal, especially with the ladies, care should be taken when fixing sheet iron to see that any portion visible at the back of the fire conforms to the general outline of the grate.

If a fire has to be fitted on a wood floor it is essential that it should be protected either by sheet iron, a concrete slab, or, better still, a tiled slab. The latter can now be obtained in a variety of shades and colours to harmonize with existing surrounds and hearths, and makes a first-class job.

In bedrooms, nurseries, and similar positions where there is a likelihood of dresses or other inflammable material coming in contact with the radiants, a fireguard should be fitted. The small

ss wire guard takes up very little ce, and is an excellent protective de- e. For nurseries or the children's play- m the heavier standard type of guard uld be advised.

A gas fire cock with loose key is safer n the usual thumb cock. The latter be easily turned by children, and even the process of sweeping the floor. The bability may be remote, but the possi- ity is present.

Full-way union cocks should always be d, for obvious reasons.

With regard to the running of supplies oss hearths, much depends upon cir- nstances. In the case of new houses, where alterations to the grate and arth are in progress in others, it is ad- able, if not essential, that the supply uld be carried under the hearth to a table position before the tiles are laid. may mean extra trouble and expense, t will be seen to have been worth while en the job is finished.

Regarding the type of fire, thanks to e makers, who are to be congratulated their productions from the viewpoints efficiency, design, and finish, there are ny types to choose from. As every ss of consumer is now catered for, the ection should be easy. In the case of es rented on simple-hire terms, the ailable patterns may be narrowed down a certain few; but even here the choice not a difficult one.

Where the consumer personally visits showroom to inspect the various types fires, the fullest particulars should be tained by the salesman regarding size d aspect of room, together with any formation in the matter of outside walls d glass surface, and also the purpose r which the room is used—*i.e.*, whether quired to be heated quickly and only ed for a short time, or whether longer riods can be taken in the heating-up. This will enable him to recommend fire of suitable size, and also saves the tside man a lot of extra work should it necessary to re-select the fire on the emises. Where the latter has to be one, the impression created on the con- mer is not a good one, nor does it assist e good relationship which should exist tween the indoor and outdoor staffs. here the order is taken actually on the emises, the district man will, of course, ve no difficulty in recommending the ght fire.

If, after discussing the matter at his use, the consumer requires to see the e before placing the order, an appoint- ent should be made for a meeting in the owroom. Whenever possible, of course, e outdoor representative will meet his stomer. Should this not be convenient, owever, we, in Birmingham, invite the ient to call to see a certain salesman ho has previously been supplied with all e facts of the case, and is therefore ady for the interview. It is found that this method much unnecessary delay saved, the customer can be shown suit- ble models right away, and further, ap- reciates what may seem a special atten- on.

Where it is desired to cover up an open- ng or grate, quite a good job can be made ith the art metal surrounds now avail- ble. A new shade called "white finish" particularly suitable for the "art lver" fires; and it is possible to com- lete the set with hearth plate and curb match. Customers should be advised ot to allow articles to be dragged across he hearth plate, as scratches are easily ade.

It is worth remembering that an ugly r unsuitable grate will utterly spoil the ppearance of a nicely-finished high-grade re. To quote but one instance, a client ished to have an art silver finished fire nstalled in a room where there existed a roken-down black grate. He was ad- ised to have an art metal surround fitted, n order to make a good job of it. Not wishing to go to this expense, he decided to put up with the appearance, and left his order. Before he left the building, however, a few words warned him of the disappointing appearance which would result from his choice, and he was asked to think it over. He did, and the result was an order for a surround and hearth plate to match. He later called and expressed his satisfaction with the installation.

Regarding duplex taps, I personally think it advisable, where the size of the room and the purpose of its use permit, to recommend the larger size with duplex tap. The increased radiant surface allows of quicker heating up, the duplex can be put into action, and the room kept at a suitable temperature on a reduced consumption. It has been found that a drop in efficiency occurs when the flame is turned-down below three-quarters of its full capacity, and, as regards appearance, who would prefer the half-dead aspect of a turned-down flame to the very much alive appearance of fully-fed radiants, even though the latter may be reduced in number?

At least one bedroom fire should be fitted with a boiling burner.

Flueless stoves, radiators, &c., should only be allowed in well-ventilated halls, corridors, and such places, and not in bedrooms and apartments where, if used for a long time, their convected heat would tend to warm up the air unduly, to the discomfort of the occupants.

We are sometimes asked to fit apparatus of the radiator type in large rooms, to assist either a coal or a gas fire. Though not ideal, I see no reason against this, provided the client is made fully aware of our ideas on the question of radiators in living rooms. A syphon stove so fitted would answer admirably; but if the consumer insists on a gas-heated radiator, the fullest instructions should be given regarding the cleaning of the burners, with a view to preventing as far as possible any unpleasant odour. The floor and wall should be protected, and a wall shield added in the case of a radiator, to minimize discolouration of the wallpaper.

A word of caution regarding syphon stoves. The burner fitted is of the governor type, and made to pass a certain volume of gas. Should the governor get out of action, and allow a greater quantity of gas to pass, serious sooting-up will occur.

Other heaters of the flueless type are now to be found everywhere, but, though they are admirable things when used under proper conditions as regards ventilation, position, &c., the greatest care should be exercised to see that their sphere of usefulness is fully pointed out to a customer.

Hot Water.

The demand for hot water in the home is a very pressing one. The generally accepted method of obtaining it is by means of the kitchen range boiler. This may not be a matter of great moment to owners of large residences where servants are kept, but to the little English servantless home it is an entirely different matter.

The coal range at its best is a dirty, extravagant, labour-making business, requiring more or less constant attention, and the dreaded job of cleaning flues. That this is being realized is evidenced by the increasing number of hot water appliances now being installed in both old and new houses.

For a one-point service such as the bath, the geyser is the best apparatus; for two points such as a bath and a scullery sink, a geyser and one of the small but useful patterns of water heaters is specially adapted for this purpose. In the case of a house requiring several positions to be served, then we have the circulator or "Califont" boiler.

Taking the bath first, we have in the geyser just the means of supplying the necessary quantity of hot water quicker and cheaper than by any other means. There are many different patterns to choose from, and I should like to make a few observations on their selection and use. Let the pattern you sell be of approved quality, and do not stint the price. Cheapness in a geyser refers to price only—they are dearer in the long run. Do not recommend one of small capacity. The three to four gallons per minute size has been found the minimum for general use. It costs a little more, but the point which is very frequently forgotten is that the makers' average claim is a rise of 40° Fahr. only for the stated capacity. Let me put it another way. Suppose you sell a geyser rated at 2½ gallons per minute. In the summer months the temperature of the water at the inlet may be 55° to 60° Fahr. Allowing a rise of 40°, and an outlet temperature of 100° Fahr., it will take approximately ten minutes to obtain 25 gallons.

Suppose the geyser is required during the winter, the inlet temperature will now be nearer 40° Fahr., which, with the 40° rise, gives us an outlet temperature of only 80° Fahr. In order to bring this up to our 100° Fahr., we reduce the flow to about 1¾ gallons per minute—thus taking over fifteen minutes to supply the 25 gallons. This is equal to an increase of over 50 p.ct. in the time the apparatus is working. It will thus be seen that the life of the small geyser will be very much shorter, and the time taken to supply the hot water longer, than is the case with the larger apparatus. Many people require water at considerably higher temperature than 100° Fahr., and it has been found in practice that, during the colder periods, the 2½-gallon size takes even twenty minutes, whereas we should aim at a ten minutes' maximum. With regard to this guaranteed supply, I consider it would be an advantage if the makers arranged for a greater rise than 40° in the capacity ratings.

A geyser should preferably be fitted with a dual gas and water valve, ensuring immunity from damage should the water supply either fail or be turned off. Interlocking taps, if soundly and strongly made, and of good design, are safe enough, but there is always the possibility of damage to the apparatus should the water fail.

The fixing of geysers is dealt with very thoroughly in the pamphlet recently issued by the National Gas Council, of which doubtless all of you have a copy.

If the only other point at which hot water is required is the sink, then a "Hotwell" or similar boiler will fill the gap. This comprises a self-filling tank of varying capacity; and a quick-acting thermostat is also part of the equipment. This comes into action on the water becoming heated to a predetermined temperature, usually hot enough for dish-washing purposes, when the gas is reduced to an amount sufficient to maintain the water at that temperature. The reverse happens when the hot water is drawn off.

With these two appliances the demands of the small home can be met very readily. Should the geyser be required to serve the lavatory basin as well as the bath, this can sometimes be done by means of a swivel spout.

Where hot water is required throughout the house, from a single apparatus, a gas-heated circulator is as a rule fitted. This can be connected up to the existing hot water pipes. In Birmingham we prefer to run a separate flow pipe from the circulator to the hot water tank, thus ensuring the hot water getting there quickly—it can always be run off when once available.

Care should be taken to see that a large enough boiler is put in. It is no use fix-

ing a 40 c.ft. boiler to a 40 or 50 gallon tank, and expecting it to be an advertisement for gas. It is far better to supply one double this size, or reduce the capacity of the tank. For tanks up to 30 gallons, the 40 c.ft. size will be suitable, and for larger capacities the 80 c.ft. Thermostats are not to be recommended on the small circulator unless special attention is paid to the lagging of the pipes, with a view to preventing heat losses by radiation. Unless this is done, the radiation losses from pipes and hot tank may easily demand sufficient gas to make good such losses, and thus prevent the thermostat from coming into action. In the case of the larger boiler feeding a tank up to 45 gallons capacity, the thermostat would effect a saving; but steps should be taken to protect any long lengths of exposed piping, as well as the tank itself. It is the gas account at the end of the quarter which induces the customer to retain his confidence in the circulator—or otherwise. The question of labour saving, cleanliness, and convenience seems to be forgotten; the degree of such forgetfulness being influenced by the amount of the gas bill.

Another type of water heater for bath purposes is the pattern which contains some 8 or 10 gallons, which, after being heated-up, is expelled by the admission of cold water. The objection to this type is that the whole of the contents have to be heated, and the quantity of water available is dependent upon the size of the heater installed. Unless specially adapted for the purpose, as is done in a few patterns, small quantities cannot be obtained.

Outside taps and levers should be as simple as possible on all hot water apparatus. The public have no great liking for complicated pieces of mechanism.

With regard to fitting charges. As in the majority of cases the prospective purchaser first calls in the showroom for particulars as to cost and capabilities, I suggest that it would be in the interests of all undertakings if information regarding the approximate cost of fixing be supplied to the showroom assistants from time to time. Any misunderstanding regarding free fixing would thus be obviated. A better plan, of course, would be a standard price for the job, as is done in some of the southern counties, but possibly this will come along in our own area later. I am convinced that the high cost of fixing is, at the moment, a deterrent to many who would otherwise have hot water appliances installed.

My last water heater is the "Califont" boiler. Though we in the Midlands are not so well acquainted with it as are the people in London and the South, we cannot afford to ignore such an appliance, which, according to the opinion of users, is an excellent piece of apparatus for supplying hot water to all parts of the house. Working on the geyser principle, the gas is automatically switched on when hot water is drawn off, the closing of the tap reducing the gas again, resulting in economical working. Its consumption, when full on, is about the same as the largest geyser—viz., about 240 c.ft. per hour.

Wash Boilers.

In newly-built property the gas wash boiler is a foregone conclusion, and each day sees an increase in the number of boilers replacing the old solid fuel copper. There are possibly more individual firms making wash boilers than any other piece of gas apparatus. The wash boiler is a typical case of the urgent need for legislative interference in order to check the flow of galvanized contraptions which are being foisted on the public to-day, mostly by the speculative builder, whose interest ceases when the house is sold. Fortunately, housing authorities are now insisting on a better type of boiler than was the case a year or so ago. Inferior stuff is bound to react upon us, even though we have not had a say in the matter.

There are, however, some really excellent types on the market. Most of you have, I dare say, your own particular liking for certain models; and it is rarely that the better types made by firms of repute fail to give satisfaction.

All wash boilers should be fitted with draw-off taps, to facilitate emptying. Flue outlets are essential for the proper and complete discharge of steam and products of combustion. Loose wooden lids are preferable to metal. In those types fitted with a galvanized iron lid hinged at the back, there is a danger of scalding due to the uprush of steam into the face of the user, on the lid being raised. A wooden lid can be used as a guard.

A flue pipe should be taken from the boiler to the nearest chimney, or, failing this, through the wall. The terminating portion must be fitted with an efficient cowl or other device, to prevent down-draught. A lagged case will greatly assist in the economical working of the boiler, and will also keep the scullery cooler. Where space is a consideration, the new "Corna" boiler has its advantages. As with other gas apparatus, the best is the cheapest in the end.

Garage Heating.

The necessity for the proper heating of the garage—whether large or small—is becoming more generally realized. The fire insurance companies are naturally very strict concerning the type of heater to be installed, so that it behoves all undertakings to act warily, if unpleasant happenings are to be avoided.

We have at our disposal, among others, the Davis "Safety Garage" radiator, which can be confidently recommended both as to its efficient working and immunity from danger. Further, this appliance has been passed by several insurance companies in Birmingham. As you are aware, it is constructed on the principle of the Davy safety lamp; the air inlet at the bottom being covered with gauze, and the hot gases, after heating the cast-iron columns, passing away through the gauze-covered openings at the top. It is made in both two and four column sizes.

The heater will invariably be fixed at the end of the garage nearest to the radiator of the car; and if the ventilation of the building is normal, no trouble need be anticipated regarding the products.

Gas Irons.

While we cannot claim the gas iron as a means of increasing consumption, it enables us to obtain the goodwill of the housewife or other user, and thus assists in promoting amicable relationship between the undertaking and the consumer. There is, however, one proviso—viz., the iron must be an efficient one. If it is not, it can become a veritable nuisance.

It should be of just sufficient weight to enable it to be used for fairly long periods without fatigue. The burner should be capable of giving an easily regulated heat evenly distributed over the bottom of the iron. It should be capable of easy adjustment when necessary, and the method of doing this should be explained at the time of purchase. All metal parts should be nickelled, to prevent rusting.

I do not advise the use of a two-way tap above an inverted burner. I know it has been, and is being, done, but there is always the risk of vibrations from the movement of the flex being conducted to the mantle.

Towel Rails.

A gas-heated towel rail in a bathroom is a very convenient article.

Ewarts' new pattern consists of hollow tubes conforming to the appearance and shape of the usual towel rail, and is entirely self-contained, both as regards water and gas. One upright serves as a filling point for the water, and a luminous burner of about 5 c.ft. capacity is fit in the bottom of the other upright, spec provision being made for the escape waste products.

Miscellaneous.

We have the poker burner and the ci ing-iron heater. For the man there is neat little bracket with bunsen burn attached to which is a supporting ring accommodate a shaving mug. T bracket is nickel-plated, and the mug is aluminium.

Discussion.

Mr. Lewis (Birmingham), opening the d cussion, said that lighting did not get sufficie advertisement—at least, it did not get t same amount of advertisement as did other g apparatus. While they could still retain in make a profit by other apparatus, it was esse tial that they should do their utmost to reta the lighting load; and this could be done always advising good fittings. For econon and artistic lighting gas could still put up good fight. One of the chief things to strive for in gas apparatus was simplicity.

Mr. Ramsden was very pleased that h Directors had shown their appreciation of th Circle's visit by their presence. He was als pleased to see present Mr. Rayner, late Secr tary of the Gas Light and Coke Company and the members of the local Press. He con gratulated Mr. Price on the excellence of hi paper, and thought it was so good that h would like to see copies distributed among builders, ironmongers, and architects. H would like some information about th "Teale" fire. Could the discoloration o towel rails and other apparatus be prevented?

Dr. Haynes thought it would be a good idea to read the paper to the public, in which case it would be necessary to demonstrate th apparatus mentioned. People's objection to gas fires was the smell, but he, as a doctor always recommended gas fires, and told them that the smell had nothing to do with the gas; it was a question of ventilation. In all rooms the best ventilator was the chimney. He thought it was important that a gas fire should be large enough to heat quickly and effectively the room in which it was fitted.

Mr. H. Rayner added his congratulations and thought there was a great deal in the point raised of the necessity for advertising gas fittings. When he came to Leamington he had to take over, in his house, gas fittings that were ugly, badly fixed, and expensive. It behoved them to get the most artistic fittings possible, as there was no reason why gas fittings should not be elegant and artistic, and why they should not still be a force to help the sale of gas.

Mr. Hicks (Editor of the local Press) thought that it would be better if the men sent round to fix and attend to gas apparatus would give more information with reference to little defects which occasionally arose. Having used both, he much preferred gas fires to electric heaters.

Mr. Simmonds (Dudley) remarked that architects were most important men to the gas industry. He said how important it was to exercise great care in the fixing of gas fires, particularly in the backing-in of same. Wash boilers should be pushed in all new buildings, and they should do their utmost to influence architects in this direction. Harmony between the inside and outside staffs was very necessary. Above all, they should educate the fitter and give him all necessary information.

Mr. Lewis (Birmingham) agreed with Dr. Haynes that the question of ventilation was of the utmost importance, but they must be careful not to create draughts.

Mr. Dymond (Kenilworth) said that with pneumatic switches the by-pass tubes could be improved, for, in his opinion, they were too small and were liable to choke. Speaking of geysers, builders should be educated as to the necessity for fixing baffles in all installations. He also referred to the quantity of cheap and shoddy gas wash boilers on the market.

Mr. Rees (Birmingham) said that there was a large field open for business in the installation of modern apparatus in place of the older types. It was of particular importance that up-to-date gas fires should replace the older types with ball fuel. Gas was the working man's fuel, and all the modern higher-grade types of apparatus were within the reach of everyone, on account of the hire-purchase and simple-hire systems. Mr. Rees gave some figures

iting to the deposit of soot in Birmingham, said that, while they were primarily sellers gas, by the nature of the commodity they l they were also benefactors of the public.

Mr. COBB (Birmingham) said that all wash lers should be fixed with flues, which were essential as flues for geysers. He queried ether it was good to run the steam and products in the same flue, on account of increased condensation. He also referred the condensation in water heating apparaand asked if there was any way to comit.

Mr. HAMMOND (Coventry) explained the tches in use in their area, and said that y had been entirely satisfactory.

Mr. PRICE (Birmingham) replied to the nts raised.

A vote of thanks to Mr. Price, which s carried with acclamation, was prosed by Mr. BURDEN (Redditch) and onded by Mr. BECKETT (Oswestry).

After the discussion, the showrooms re visited, the window displays being eatly admired.

The members were then entertained to , Alderman Mason, Mr. Ramsden, and . W. J. Leist (Manager of the Spa mp Rooms) being present.

Mr. LEWIS, in proposing a vote of anks to their hosts for their excellent spitality, referred to the happy relations at existed between the manufacturing le and sales side of the industry. He ought what a splendid thing it would if a smoke abatement campaign could started from Leamington, noted as it is as a health resort. What an asset it ould be to the town to be able to say at there was no smoke at all in Leaington.

Mr. SIMMONDS (Dudley) seconded.

Alderman MASON, as a medical man, id how interested he was in the quesn of atmospheric pollution. Smoke insted atmosphere was greatly responsible r that dread disease, consumption; and nce New York had adopted measures of noke prevention, the number of cases of berculosis had decreased enormously.

Mr. W. J. Leist then conducted the embers over the Pump Rooms and aths, where new installations were being ade. The various treatments were exained.

A most interesting and enjoyable visit ded with the members visiting the beauful Jephson Gardens and the river.

Good Letter Writing.—Dealing with the bject of letter writing, in the "American as Journal," Mr. William F. Doolittle, Corspondence Adviser to the People's Gas Light id Coke Company of Chicago, expresses the inion that nothing in business contributes ore towards friendly relations with customers an good letters. One incompetent corspondent can destroy goodwill more rapidly an the entire personnel of an organization n build it up. Nevertheless, letter writing, in e gas industry, is given but scant attention. he general attitude seems to be that corspondence will take care of itself. Well, he ys, maybe it will; but it will become anæmic" from lack of nourishment. Educaon is a good preventive and a good tonic, if ken in proper doses and at regular intervals. ystematic training for correspondents is slow -hill work; but it is well worth while.

New Showrooms.—There will be found in is week's issue of the "JOURNAL" accounts the formal opening of two new gas showoms and offices, situated in different parts the country, one of them belonging to a ompany and the other to a Corporation. The wns are, respectively, Southampton and oughborough; and each is a substantial ainer by the step forward that has thus been ken. At Southampton the Mayor performed e ceremony, which was carried out at oughborough by the Mayoress. Much care design and thoroughness of attention to deil have evidently been bestowed in both ases, for the premises are tastefully furnished nd well equipped. A hint or two may be athered from a study of the account which is iven in the "JOURNAL" of what has been one in the towns named to add to the public nowledge of what can be accomplished by as and efficient appliances.

Decorated Lorry in the Castleford Pageant.

The decorated motor lorry of the Castleford and Whitwood Gas Light and Coke Company proved a great attraction at the local pageant held on Saturday, May 16, and was awarded first prize in the tradesmen's class. A bust of William Murdoch fixed on the cab top was very prominent in the bright sunshine, as no doubt all readers will agree after examining the photograph we reproduce. The geyser on the top of the display was continually revolving, being operated from the driver's seat, and much attention was drawn to this point.

The procession, which was above a mile in length, covered approximately 3 miles *en route*, and was viewed by some immense crowds.

Mr. Geo. F. Twigg (the Company's Engineer and Manager) is confident that the exhibit was well worth the trouble and expense involved.

Maintenance Notes for Gas Salesmen.—A useful booklet, written by Mr. Charles Dickens, of the Manchester Corporation Gas Department, and published by the Palatine Press, Manchester, is based upon extracts from a number of lectures on maintenance and distribution subjects delivered by the compiler while in the service of an Australasian gas undertaking. Dealing for the most part with lighting, the booklet also contains a valuable table giving the maximum gas consumption of the more common types of gas appliances. The section relating to the capacity of meters and pipes will also be found very useful. The price of this little volume, which contains thirty illustrations, is 4d.

Scottish Circle.

In the "SALESMAN" for last month was published a paper entitled "The Gas Salesman's Attitude to Advertising," by Mr. W. M. Mason, Manager of the British Commercial Gas Association. The author intended to read this paper at the May meeting of the Circle, but was unable to attend; and the paper was read by Mr. Charles Reay, Hon. Secretary of the Circle. There was only a short discussion.

The PRESIDENT (Mr. J. Jamieson) moved a vote of thanks to Mr. Mason.

The following appointments were made for the 1925-26 session:

President.—Mr. N. S. Smith, Greenock.

Hon. Secretary.—Mr. A. B. Munro, Edinburgh.

New Members of Council.—Messrs. J. Jamieson, G. Lockhead, and J. Simpson.

Out-Door Advertising.—Persons who are anxious to ear-mark the return from each individual advertisement, should note a statement made by Mr. John F. Weedon, in the "American Gas Journal." Mr. Weedon declares that, generally speaking, it is a mistake to try to trace direct results from out-of-door advertising. They show in a gradual steady growth in the volume of business, and more particularly in a warmer and more friendly feeling on the part of the public towards the organizations. Out-of-door advertising is seen and read out of doors. People who see it are walking or riding; they are filling their lungs with oxygen, and the breezes are blowing the cobwebs from their brains. They are not thinking of business. The advertising signs they pass register on their sub-conscious mind, but they do register. One can test this out by checking-up the subjects of conversation introduced by one's travelling companions. Quite frequently one will notice matters mentioned that found their place in the mind through the medium of some billboard or poster which was recently passed, but not consciously observed.

The Pre-payment Price-changer

Pioneers in the manufacture of Slot Meters having the whole of the attachment accessible from the front.

This attachment (which is shown being fitted to a "Ranelagh" Meter at our Chelsea Works) is a slot mechanism of the highest efficiency and reliability. It is one of the chief reasons for the ever-increasing sales of the

"Ranelagh" GAS METER

There are no change wheels and there are no loose screws or parts to become detached. Alterations in the price of gas are effected (from the front of the Meter) in a few seconds. The disc has a wide range, varying from 5 to 47 feet in the penny Meter, or 60 to 564 in the shilling type.

Fixing the price-changer

Burner Equipment supplied by BRITISH FURNACES LTD CHESTERFIELD

COCHRAN

GAS-FIRED BOILER

(WOODALL-DUCKHAM-COCHRAN SYSTEM)

The Woodall-Duckham Vertical Retort and Oven Construction Co.. (1920) Ltd.

The Boiler combines all the well-known advantages of the Cochran Patent Vertical Multitubular Boiler over other boilers, with those inherent in the use of the well-known burner equipment supplied by British Furnaces Ltd., which may be briefly summarised as follows:- Saving in labour. No stoker is necessary, because the supply of gas is controlled by a governor, and the supply of water by an automatic feed regulator. There is no coal to cart to the site, no ashes to take away, and no storage space required. There is no smoke, soot, dust or dirt. The steam production can be regulated to suit demands, and when no steam is wanted, no fuel is being burned. The efficiency of the Boiler **is constant at any rate of steaming.**

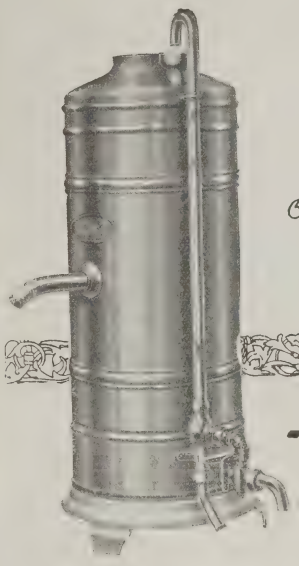
the Davis

"Shamrock"



-the geyser to choose

The Davis "New Shamrock" Geyser is an improvement on the very popular "Shamrock" model. It is constructed on the "sealed" principle, of strong copper, polished and lacquered. Interior detachable and readily accessible, with waterways heavily tinned, and standardized parts. Efficient condensation arrangement. Body rotatable to place outlet in any position.—Send for illustrated price lists.

¶

The "New Shamrock" No. 62 heats 2-2½ galls., and the No. 63 heats 3-3½ galls., per minute, *i.e.*, raises temperature of the water 40 degrees. Supplied (1) with pilot gas cock and union, (2) with interlocking taps, pilot gas cock and unions, and (3) with automatic valve, pilot gas cock and unions. The geysers can also be had in nickel-plated or oxydised bronze, if required.

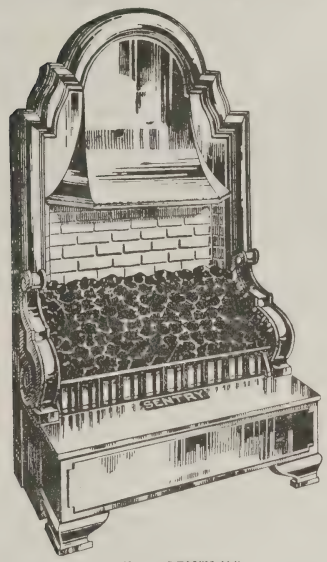
GAS FIRES



THE "SENTRY" SELF-CONTAINED GAS FIRE

A really efficient and attractive substitute to the traditional coal grate is to be found in the "SENTRY" Series of Gas Fires—made in three forms: Inset, Self-Contained, and Dog Grate.

The glowing mass of radiant fuel makes an immediate appeal to all users of Gas Fires, and perhaps what is more important, to the potential consumer who still clings to raw fuel in spite of the labour, dust, and dirt.

An interesting feature is the radiant, which is vertical for the lower 2½" before inclining backwards to carry the loose fuel—thus ensuring a maximum of radiant efficiency and reflection on the Trivet top.

The Self-Contained Fire, made in 12", 14", 16", and 18" sizes, has the appearance of a built-in fire, but is fixed by a fitter without the assistance of other tradesmen, which the built-in type frequently necessitates.

An ample hood is provided to remove the products of combustion and ventilate the apartment, giving at the same time a pleasing proportion of convected and radiant heat.

FULL PARTICULARS AND PRICES WILL BE FORWARDED ON APPLICATION.

A "SENTRY" Coke-fired Hot Water Boiler fixed in the kitchen or scullery provides hot water for all domestic purposes.

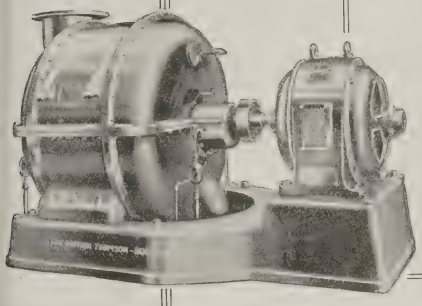
SPENCER (MELKSHAM) LIMITED
THE COAL HANDLING EXPERTS

Motor-driven Gas Exhausters



The long life of B.T.H. gas exhausters is undoubtedly due to the construction of the impeller discs and vanes, each of which is in the form of a single solid steel casting. There are no rivets to corrode or work loose, and perfect balance is continuously maintained.

Careful attention to all such details in design has reduced maintenance costs to a minimum, while ensuring constant and reliable service, even under the most strenuous conditions.

Further particulars of motor and steam-turbine driven B.T.H. gas-exhausters will be sent on request.

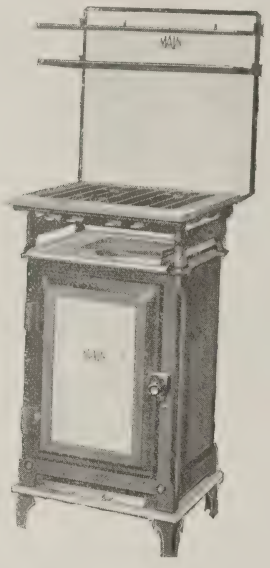
FEATURES OF THE MAIN "MAINSTAY" COOKER



The "Mainstay" Cooker, besides its handsome appearance, its efficiency in operation, and its easily cleaned exterior and interior, has many advantages that appeal to the Gas Undertakings — notably those in simplicity of construction, standardization and fewness of parts, and in interchangeability. Moreover, there is a degree of accessibility in the "Mainstay" that has won the appreciation of those who know the worries usually connected with "district" complaints and the general overhaul of Cookers.

The "Mainstay" Oven Gas Rail can be disconnected and removed in a moment. The packing can be inspected by simply removing the back. The undertop is removable, and can be taken out by loosening its one screw with the thumb and forefinger. The Cooker can be dismantled entirely in five minutes, or dismantled and re-assembled in a quarter of an hour.

The story of the "Mainstay" Booklet illustrates and describes many other interesting features of this popular Cooker. Send a postcard for a copy.

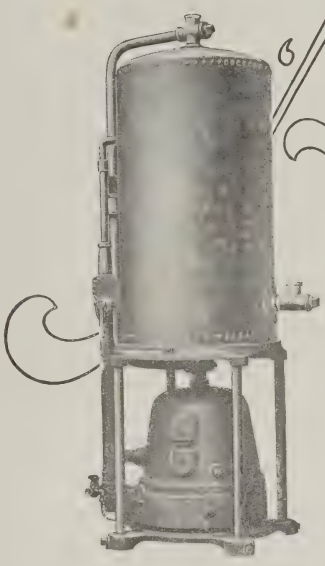
Arden Hill's "Acmefont" — the Simplicity Builder's Set



This economical gas-heated hot-water outfit cannot be surpassed for simplicity and reliable working. It is "built like a battleship," for service and hard wear. It requires few connections, and the gas supply is controlled by a patent Thermostat.

Fitted with economy valve, allowing 5 galls. or whole contents to be heated at will.

Provision for connecting to existing coal-range boiler, if required.

Storage cylinders of galvanized iron, or copper for soft-water districts. Supplied on high or low stands.

Advice will gladly be given as to installing problems, on application.

"ACMEFONT"

HUMPHREYS & GLASGOW LTD.

LABOURLESS AUTOMATIC { Self-Charging / Self-Steaming / Self-Clinkering / Self-Operating } CARBURETTED WATER-GAS PLANT!

Self-Charging Water-Gas Plant:

Automatic Charging and Distributing of the Fuel, *without interruption of the gas-making process*, eliminates coking labour, increases capacity, and ensures constant conditions of maximum efficiency in tops of generator and carburetter;

Self-Steaming Water-Gas Plant:

By making Steam Generators a corporate part of H. & G. Water-Gas Generating Plant, the steam for the entire Plant is produced without cost. Moreover, *in addition to saving all boiler fuel and labour*, these Steam Generators (unlike independently fired boilers) do not require boiler house or setting or chimney, or fuel and ash handling apparatus;

Self-Clinkering Water-Gas Plant:

Throughout the history of Water-Gas, Clinkering has been the great bugbear, aggregating per Generator several hours daily of arduous labour, and causing corresponding loss of capacity, waste of fuel, wear and tear on plant and tools, and general disorganization and uncleanliness; all previous attempts to eliminate it having failed, strenuous Hand-Clinkering has come to be regarded as the inherent defect of the Process. Even with *Carburetted* Water-Gas *the H. & G. Self-Clinkering Generator Completely Eliminates All Clinkering Trouble, Labour and Expense.* It maintains a constant condition of maximum efficiency throughout the fuel-bed, while minimizing the carbon in the clinker automatically discharged from the Generator —without circulation of cooling water, or waste of heat, water or steam. It also accomplishes perfect distribution of the generator air-blast. While largely increasing capacity, it does not require periodical repairs to linings, as in the case of other water-gas generators. *No fire-tools are required; the fuel-bed is never disturbed;*

Self-Operating Water-Gas Plant:

H. & G. Automatic Operation eliminates gas-making labour, substitutes mechanical perfection for human fallibility in the regulation of the operating routine, minimizes the cyclical extremes of temperature in the fuel-bed, improves the fuel and oil efficiencies, and increases the capacity of the Plant—*all while ensuring the Safety of the Process.*

(Patents granted or applied for in the various Countries.)

Head Office: 38, VICTORIA STREET, LONDON, S.W. 1.

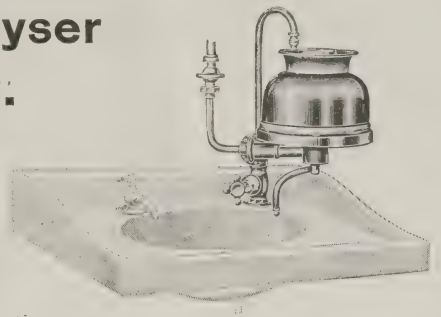
The "HENDON" Geyser

(TILLEY'S PATENT)

is something new.

IT IS FIXED IN PLACE OF ONE OF THE TAPS.



The "Hendon" Geyser is an instantaneous Water Heater, at a small cost, specially designed for the immediate supply of **small** quantities of hot water. It fits the Water Supply of any Lavatory Basin or Sink, and raises the temperature of a gallon of water 60° F. in 4½ minutes. As the water cannot come into contact with the products of combustion, the water as it leaves the Geyser is as pure as when it entered and may therefore be used for drinking and all domestic purposes. Just light the Gas Bye-Pass and turn the Tap and the flow of hot water starts and continues as long as you like.

The "Hendon" Geyser is the perfection of simplicity, reliability, and freedom from trouble. The first cost is low, it is economical in use, and, above all, is perfectly safe.

It is invaluable in the Home and for Doctors, Dentists, Hairdressers, and others to whom a constant supply of hot water is essential. It is finished in polished brass or white enamel.

HOW TO FIX IT.

The plumbing work necessary with all other sink Geysers is abolished. The "Hendon" is fitted to the Water Supply of any Lavatory Basin or Sink merely by screwing the connection to the Union Joint of the Tap, thus making a permanent fixture. It may be fitted in any position in relation to the Basin and Sink, the fitter only needing to arrange parts to suit requirements. When the Copper container becomes furred or needs cleaning, it may be detached immediately and another substituted while it is cleaned.
